The work presented in this document was carried out in accordance with the Windtech Consultants Quality Assurance System, which is based on International Standard ISO 9001.

This document is issued subject to review and authorisation by the Team Leader noted by the initials printed in the last column above. If no initials appear, this document shall be considered as preliminary or draft only and no reliance shall be placed upon it other than for information to be verified later.

This document is prepared for our Client's particular requirements which are based on a specific brief with limitations as agreed to with the Client. It is not intended for and should not be relied upon by a third party and no responsibility is undertaken to any third party without prior consent provided by Windtech Consultants. The information herein should not be reproduced, presented or reviewed except in full. Prior to passing on to a third party, the Client is to fully inform the third party of the specific brief and limitations associated with the commission.

EXECUTIVE SUMMARY

This report presents the results of the natural ventilation wind tunnel study of the 2 Mandala Parade development located in Castle Hill. The natural ventilation performance of the development has been assessed by calculating the hourly mean difference in pressures acting on the various openings of each unit. The results are presented as tabulated mean differential pressures between openings for each unit.

The mean pressures have been subjected to a directional probability weighting summed over the various wind directions to calculate the 50th percentile pressures within the target wind model. The target wind model includes all wind events that occur between temperatures of 20°C to 29.5°C, which are the conditions when occupants are mostly likely to utilise natural ventilation to regulate thermal comfort. Note that the target wind model shows a decreased influence of the westerly winds, which are prevalent during the colder months.

Testing was performed at Windtech's boundary layer wind tunnel facility. The wind tunnel has a 3.0m wide working section and a fetch length of 14m, and measurements were taken from 16 wind directions at 22.5 degree increments. Testing was carried out using a 1:300 scale model of the development. The effects of nearby buildings and land topography have been accounted for through the use of a proximity model which represents an area with a radius of 375m.

The wind tunnel study models of the buildings were fitted with a total of 325 pressure sensors spread across the external openings for the natural ventilation analysis. The mean pressure differentials were calculated for each wind direction using a total of 981 flow paths.

The results of the initial study indicate that 60% of units (114 out of 189) are deemed to satisfy the guidelines set out in the Apartment Design Guide (ADG) for openings on opposite or orthogonal aspects. When compared to these units, an additional 8% of units (15 out of 189) also have a significant pressure differential at the openings that is equivalent or better than a unit that is deemed to satisfy the ADG. Therefore, the development can achieve a total of 68% (129 out of 189) of residential apartments that satisfy the ADG requirements for natural cross-ventilation through locating openings in significantly different pressure regions such as the proposed plenum ducts.

Appendix F Methodology

INTRODUCTION

A wind tunnel study has been undertaken for the determination of the mean external pressures acting on the various openings of the subject development. The test procedures followed for this wind tunnel study were based on the guidelines set out in the Australasian Wind Engineering Society Quality Assurance Manual (AWES-QAM-1-2019), ASCE-7-16 (Chapter C31), and CTBUH (2013). Further details of the wind tunnel data acquisition procedure are provided in Appendix F.

The close agreement between Windtech's wind tunnel pressure measurement results and full-scale data observed from the Texas Tech Experimental Building provides some indication of the accuracy of Windtech's wind tunnel results (A.W. Rofail, 1995). Windtech's pressure results show the closest recorded comparison to full-scale results, within an accuracy of $\pm 5\%$.

A scale model of the development was prepared, including the surrounding buildings and land topography. The model was fitted with pressure sensors spread across the external openings on the façade of the development. Testing was performed at Windtech's boundary layer wind tunnel facility. The wind tunnel has a 3.0m wide working section and a fetch length of 14m. Measurements were taken from 16 wind directions at 22.5-degree increments, and the wind tunnel was configured to the appropriate boundary layer wind profile. All pressures were measured simultaneously. Mean external pressure coefficients were obtained from the wind tunnel measurements for each individual pressure sensor for each wind direction tested. Tabulated results and plots of the recorded directional pressure coefficients are provided in Appendix A for each pressure sensor. Further details on how the pressure coefficients are defined are provided in Appendix F.

WIND TUNNEL MODEL

Wind tunnel testing was carried out using a 1:300 scale model of the development and surroundings. The study model incorporates all necessary architectural features on the façade of the development to ensure an accurate wind flow is achieved around the model, and was constructed using a Computer Aided Manufacturing (CAM) process to ensure that a high level of detail and accuracy is achieved. The effect of nearby buildings and land topography has been accounted for through the use of a proximity model, which represents a radius of 375m from the development site. It is noted that several other developments are proposed nearby, and hence testing for this tower was conducted with those proposed development taken into consideration.

Photographs of the wind tunnel model are presented in Figures 1. A plan of the proximity model is provided in Figure 2.

The wind tunnel study model of the building was fitted with a total of 325 pressure sensors spread across the external openings for the natural ventilation analysis. The mean pressure differentials were calculated for each wind direction using 935 flow paths, assuming an annual median probability of occurrence. These calculations are for wind events that occur when temperatures are between 20°C to 29.5°C, which are the conditions when occupants are mostly likely to utilise natural ventilation. This has been further detailed in Section 4.

The name and location of these pressure sensors are shown in the form of marked-up drawings in Appendix C.1.

BOUNDARY LAYER WIND PROFILES AT THE SITE

The roughness of the surface of the earth has the effect of slowing down the wind near the ground. This effect is observed up to the boundary layer height, which can range between 500m to 3km above the earth's surface depending on the roughness of the surface (i.e. oceans, open farmland, etc.). Within this range the prevailing wind forms a boundary layer wind profile.

Various wind codes and standards and other publications classify various types of boundary layer wind flows depending on the surface roughness z_0 . Descriptions of typical boundary layer wind profiles, based on D.M. Deaves and R.I. Harris (1978), are summarised as follows:

- Flat terrain ($0.002m < z_0 < 0.003m$). Examples include inland water bodies such as lakes, dams, rivers, etc., and the open ocean.
- Semi-open terrain ($0.006m < z_0 < 0.01m$). Examples include flat deserts and plains.
- Open terrain ($0.02m < z_0 < 0.03m$). Examples include grassy fields, semi-flat plains, and open farmland (without buildings or trees).
- Semi-suburban/semi-forest terrain ($0.06m < z_0 < 0.1m$). Examples include farm land with scattered trees and buildings and very low-density suburban areas.
- Suburban/forest terrain ($0.2m < z_0 < 0.3m$). Examples include suburban areas of towns and areas with dense vegetation such as forests, bushland, etc.
- Semi-urban terrain ($0.6m < z_0 < 1.0m$). Examples include centres of small cities, industrial parks, etc.
- Urban terrain ($2.0m < z_0 < 3.0m$). Examples include centres of large cities with many high-rise towers, and also areas with many closely-spaced mid-rise buildings.

The boundary layer wind profile does not change instantly due to changes in the terrain roughness. It can take many kilometres (at least 100km) of a constant surface roughness for the boundary layer wind profile to achieve a state of equilibrium. Hence an analysis of the effect of changes in the upwind terrain roughness is necessary to determine an accurate boundary layer wind profile at the development site location.

For this study this has been undertaken based on the method given in ESDU-82026:2002 and ESDU-83045:2002. Aerial images showing the surrounding terrain are presented in Figures 3 for ranges of 5km and 50km from the edge of the proximity model used for the wind tunnel study. The resulting mean and gust terrain and height multipliers at the site location are presented in Table 1, referenced to the study reference height of 70.3m. Note that the approaching winds to the site vary in speed with respect to height above ground. For each of the 16 wind directions tested in this study, the approaching boundary layer wind profiles modelled in the wind tunnel closely matched the profiles listed in Table 1. Plots of the boundary layer wind profiles used for the wind tunnel testing are presented in Appendix D of this report.

REGIONAL WIND MODEL

The regional wind model used in this study was determined from an analysis of measured directional mean wind speeds obtained at the meteorological recording station located at Bankstown Airport. Data was collected from 1993 to 2016, excluding wind events outside of the temperature range from 20°C to 29.5°C, and corrected so that it represents wind speeds over standard open terrain at a height of 10m above ground for each wind direction. From this analysis directional frequencies of occurrence for the region are determined and are presented in Figure 4. The calculations presented in this report are based on the directional wind speed event frequency table.

The wind climate data indicates that the north-easterly and south-easterly winds are the most frequent winds for the region during warmer weather. The temperature range was selected to represent the warmer conditions when natural ventilation is most desirable to improve occupant thermal comfort.

Table 2: Directional Probabilities of Occurrence of Wind Events

5 NATURAL VENTILATION PRINCIPLES AND CRITERIA

Natural ventilation is a primary design concept to reduce or remove the requirement for mechanical ventilation and/or air-conditioning of a building. This provides an environmental benefit by reducing greenhouse gas emissions due to the constant demand for mechanical ventilation and air-conditioning by the occupants. Natural ventilation is not only environmentally beneficial but also has financial benefits in terms of both construction and running costs of the development. Although a naturally ventilated designed building will require more window openings, the benefit of not having to install mechanical ventilation units greatly outweighs this cost. Running costs are also reduced with no ongoing mechanical ventilators and benefits from reduced reliance on artificial lighting (Peddie and Rofail, 2010)

Natural ventilation of indoor areas can be used to improve both the level of occupant comfort and the air quality of an internal space. It is also beneficial in improving occupant comfort during warmer temperatures when the occupants will generally have windows and doors open, while during cooler temperatures it is considered primarily beneficial for air quality purposes only. The predominant wind directions for the region have been analysed in Section 4 of this report.

Furthermore, it has been found that a naturally ventilated building reduces what is commonly known as Sick Building Syndrome (SBS) (Chenvidyakarn, 2010 and Awbi, 2010). Occupants of mechanical or air-conditioned buildings are known to be susceptible to symptoms including itchy eyes, coughs, sneezes and drowsiness. This commonly leads to lower productivity or higher incidences of sickness than when compared to naturally ventilated buildings.

The NSW State Environmental Planning Policy No. 65 (SEPP65) Apartment Design Guide (ADG) states that, for a development to be considered naturally ventilated, at least 60% of the individual apartments in the first nine storeys of the building must be considered to be naturally cross ventilated. Apartments at ten storeys or greater are deemed to be cross ventilated only if any enclosure of the balconies at these levels allows adequate natural ventilation and cannot be fully enclosed.

The ADG states that natural cross ventilation is achieved by apartments having more than one aspect with direct exposure to the prevailing winds, or windows located in significantly different pressure regions, rather than relying on purely wind driven air. Examples of apartments which are classified as being naturally cross ventilated by SEPP65 are shown in Figures 5a and 5b below, which also show examples of flow paths for natural cross ventilation through the apartments.

The ADG does provide design guidance for the layout and design of single aspect apartments to maximise natural ventilation. While these are not considered naturally cross ventilated, they provide guidance in situations where there are site restraints to achieve design excellence in single aspect apartments. The design allows for the inclusion of plenums, vertical ventilation shafts and building indentations with a width to depth ratio of 2:1 or 3:1 to ensure effective air circulation and avoid trapped smells.

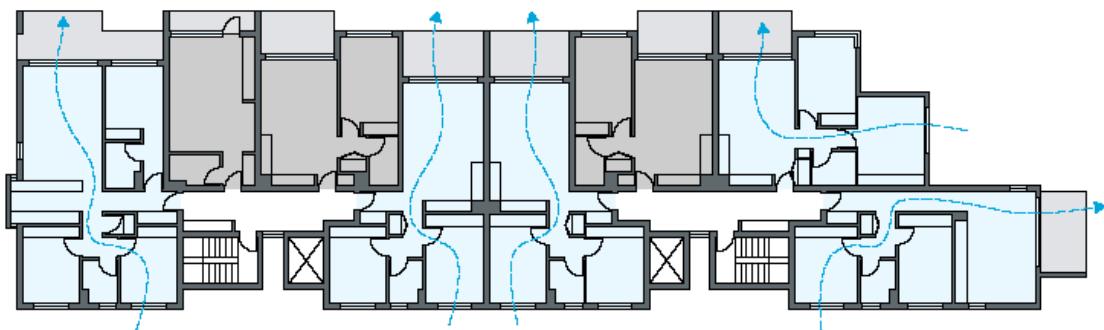

Figure 5a: Examples of Apartments Achieving Effective Natural Cross Ventilation
(from ADG, floor plan of a typical residential building)

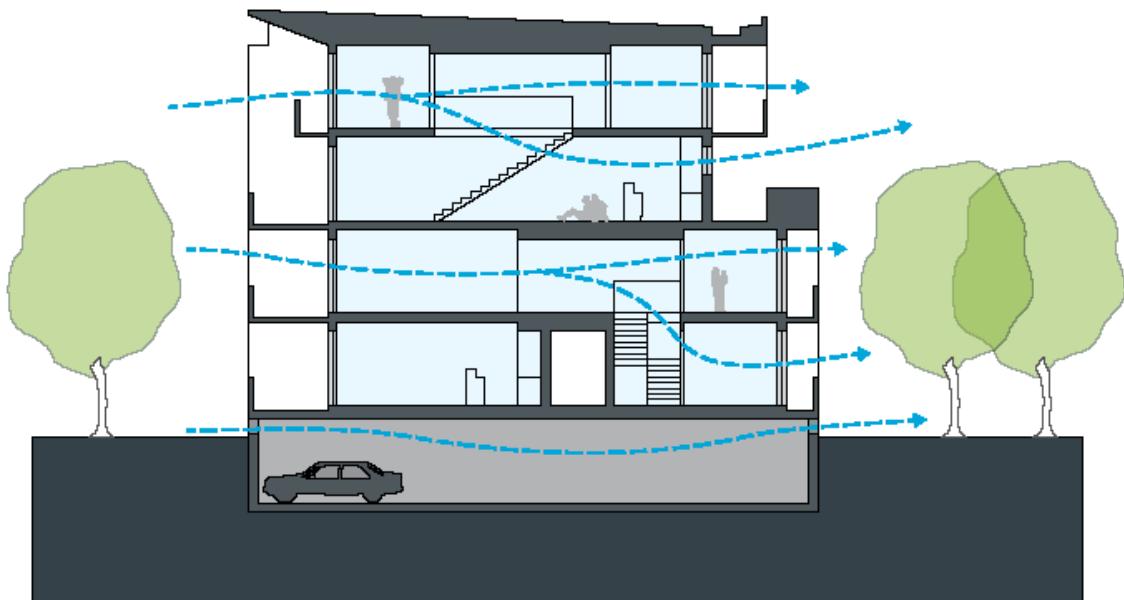

Figure 5b: Examples of Apartments Achieving Effective Natural Cross Ventilation
(from ADG, section of a typical residential building)

To be effective, the ventilating flow paths in an apartment should flow through the entire apartment, particularly the bedrooms and living spaces, driven by a significant pressure differential at the openings. According to the ADG, the flow paths should generally remain under 18m to maximise the air flow through the apartment. It should be noted that flow paths that flow through a bathroom have not been considered to be a valid flow path due to issues with odours.

Due to the complicated nature of flow paths driven by pressure differentials at different openings of an apartment, apartment design which are outside of those presented in Figures 5a and 5b have the potential to achieve the same or exceed the same levels of pressure differential for a flow path that satisfies the design guidance in the ADG of a deemed to satisfy apartment, and therefore provide effective natural ventilation.

RESULTS AND DISCUSSION

The results of the study for each individual apartment are shown in Tables 3. The flow path achieving the highest pressure differential has been presented for each apartment being assessed against the units that are deemed to satisfy the ADG. The mean pressure differential (ΔP) for a 50% probability of occurrence has been given in pascals (Pa), where flow paths that meet the requirements of the ADG have been deemed to satisfy. The results for all other apartments have been compared to a pressure differential for a flow path that clearly satisfies all the requirements of the ADG. The selected mean differential pressure for an apartment which satisfies the guidelines of the ADG is 0.44Pa.

Each flow path analysed has been included in Appendix B, where for each apartment, the various openings have been numbered sequentially in a clockwise manner around the exterior of the building, based on the architectural drawings received on April, 2022 as shown in Appendix C.2.

The results of the initial study indicate that 60% of units (114 out of 189) are deemed to satisfy the guidelines set out in the Apartment Design Guide (ADG) for openings on opposite or orthogonal aspects. When compared to these units, an additional 8 of units (15 out of 189) also have a significant pressure differential at the openings that is equivalent or better than a unit that is deemed to satisfy the ADG. Therefore, the development can achieve a total of 68% (129 out of 189) of residential apartments that satisfy the ADG requirements for natural cross-ventilation through locating openings in significantly different pressure regions such as the proposed plenum ducts.

The results of the study are summarised in Table 4 as well as Appendix C.2. If in the future there is a significant change in the form of the development, the addition or alteration of the facade elements, or a significant change in the layout of surrounding buildings in the immediate vicinity, Windtech should be contacted to review the results presented in this report.

Table 4: Natural Ventilation Performance Summary

Apartments	Number	Percentage
Satisfies ADG (Deemed to Satisfy)	114	60.3%
Significant Pressure Differential	15	7.9%
No Significant Pressure Differential	60	31.7%
Naturally Cross Ventilated	129	68.3%

APPENDIX D FLOW PERFORMANCE THROUGH A TYPICAL APARTMENT

Table D.1: Table of Relative Flow Performance through a Typical Apartment

Flow Path through Typical Apartment	Description	Comparative Pressure Loss	Comparative Flow Rate
Door to A	Door to 1 Sliding Window	1	1
Door to B	Door to 2 Sliding Windows	0.25	1.99
Door to C	Door to 1 Awning Window	0.25	1.99
Door to D	Door to 4 Awning Windows	0.11	2.97
Door to E	Door to Highlight Awning Window (125mm Open)	0.17	2.40
Door to F	Door to Highlight Awning Window (30° Open)	0.04	4.84
Door to G	Door to internal louvre + plenum duct + external louvre	0.86	1.08
Door to H	Door to internal louvre + external louvre only	0.74	1.16

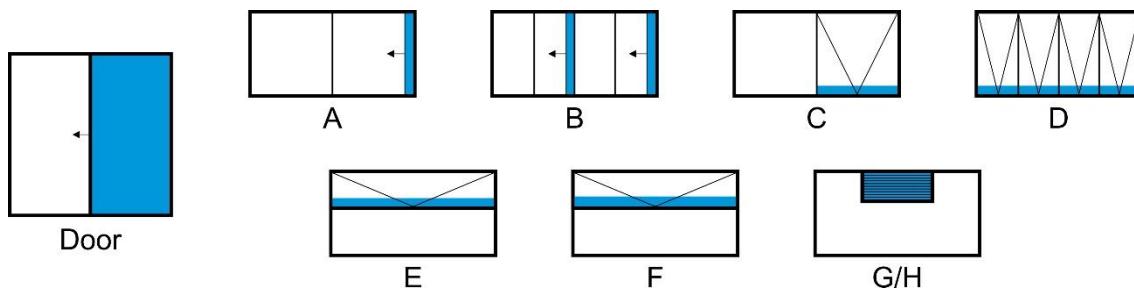

Figure D.1: Typical Balcony Door Frame Size of 2.4m×2.4m Frame Size (Door) and Typical 2nd Opening Types for a 2.4m×1.2m Overall Frame Size (A-H)

Door: Sliding door leading to a balcony (1.2m wide opening size)

A: Single sliding window with child safety device (125mm maximum opening size)

B: Double sliding windows with child safety devices (125mm maximum opening size each)

C: Single awning window with child safety device (125mm maximum opening size)

D: Four awning windows with child safety devices (125mm maximum opening size each)

E: Highlight awning window 500mm high opened out 125mm

F: Highlight awning window 500mm high opened out 30° (approx. 260mm)

G: 0.4m×1.0m internal louvre, 0.4m×1.0m plenum duct and 0.4m×1.0m external louvre

H: 0.4m×1.0m internal louvre and 0.4m×1.0m external louvre

The natural ventilation performance summarised in Table C.1 was determined for openings in series, and can be calculated from the following:

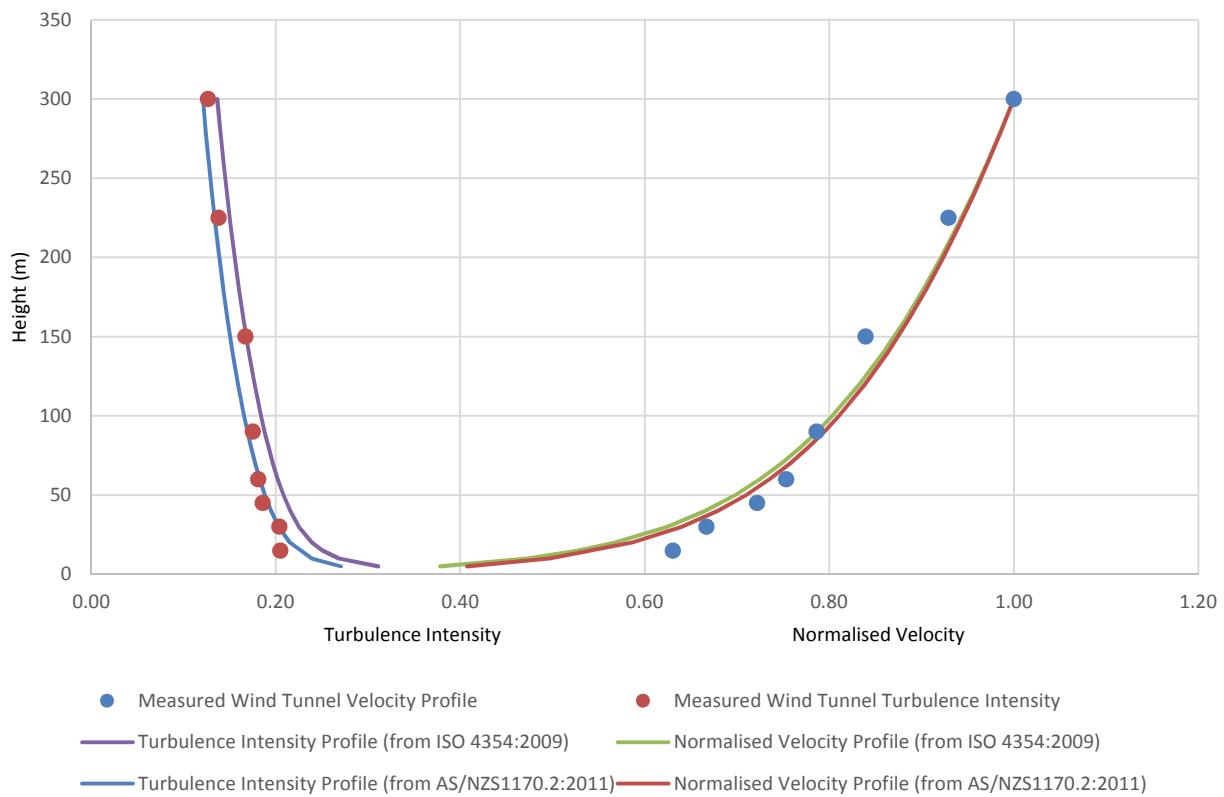

$$Q = \left[\frac{(C_{p_1} - C_{p_{n+1}}) v_h^2}{\frac{1}{C_{d_1}^2 A_1^2} + \frac{1}{C_{d_2}^2 A_2^2} + \frac{1}{C_{d_3}^2 A_3^2} + \dots + \frac{1}{C_{d_n}^2 A_n^2}} \right]^{\frac{1}{2}} \quad (5.6)$$

C_{p_1}	mean pressure coefficient at Opening 1	v_h	reference mean wind speed at building height, h (m/s)
C_d	discharge coefficient of the opening	A	openable area of the opening (m ²)
Q	volumetric flow rate along the flow path through the unit (m ³ /s)	v_1	average air speed at Opening 1 (m/s)

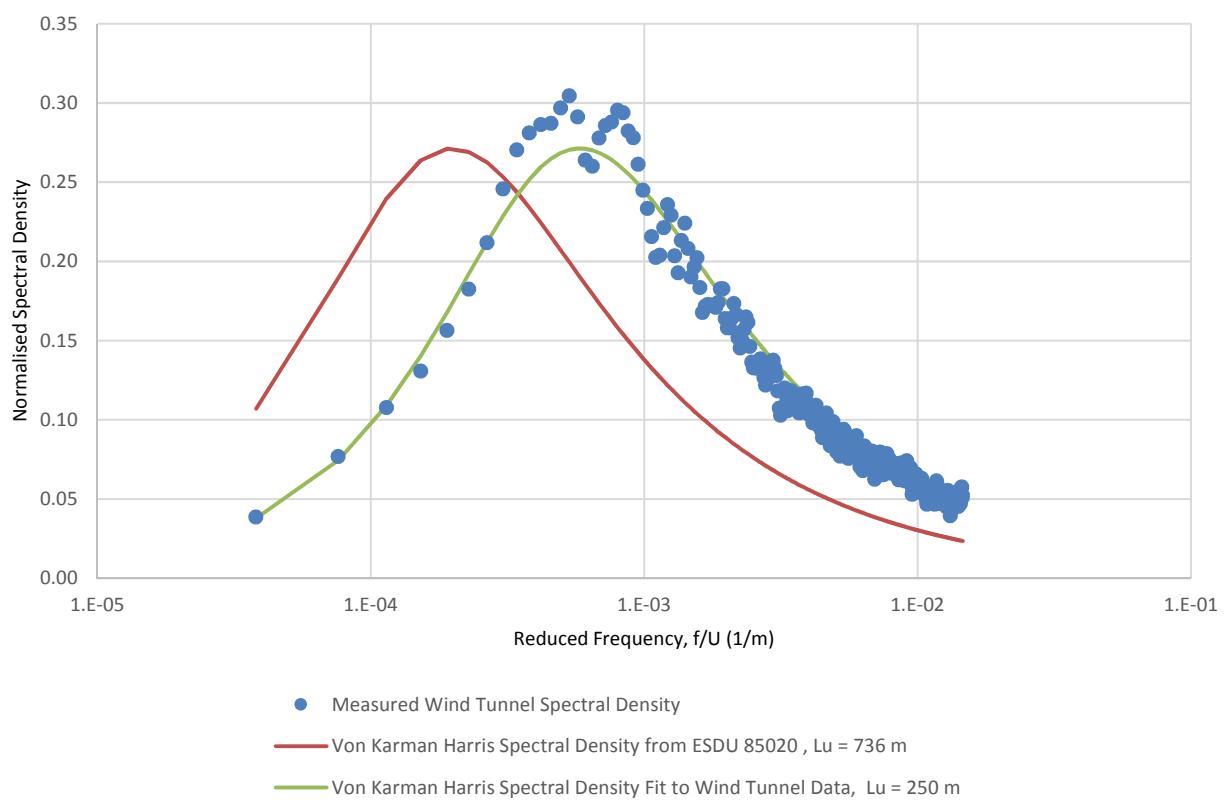

The discharge coefficient of the openings have been based on the typical opening sizes. These range from 0.7 for the balcony door and plenum duct, 0.65 for the windows, and 0.4 for the louvres.

APPENDIX E VELOCITY AND TURBULENCE INTENSITY PROFILES

**Mean Velocity and Turbulence Intensity for Suburban/Forest Terrain ($0.2m < z_0 < 0.3m$)
(TC3) at a 1:300 Scale**

Longitudinal Spectra Density for Suburban/Forest Terrain ($0.2m < z_0 < 0.3m$) (TC3) at a 1:300 Scale

APPENDIX F METHODOLOGY

F.1 Wind Tunnel Data Acquisition

Wind pressures acting on the model of the development are monitored in the wind tunnel from 16 wind directions at 22.5 degree intervals. The phase lag between the various channels where data is acquired simultaneously is within 10% of a typical pressure cycle. A sample rate of 1,024Hz is used, which is more than adequate for the given frequency band. The signal is low-pass filtered at 500Hz and then digital filtering is applied over this range to provide an unbiased response from the pressure measurement system (A.W. Rofail, 2004). This corresponds to a full-scale frequency range of approximately 0 to 4 Hz.

Based on the results of the analysis of the boundary layer wind profiles at the site, and incorporating the regional wind model, the data sampling length of the wind tunnel test for each wind direction corresponds to a full-scale sample length of at least 30 minutes. Research by A.W. Rofail and K.C.S. Kwok (1991) has shown that the mean wind is stable for sample lengths of 30 minutes or more (full-scale).

Mean external pressure coefficients are obtained from the wind tunnel measurements for each individual pressure sensor for each wind direction tested. The application of wind tunnel testing for the modelling of natural ventilation has been reported previously by Rofail and Aurelius (2004) and Peddie and Rofail (2010 and 2011).

F.2 Calculation of the Pressure Coefficients

The mean external pressure coefficients obtained from the wind tunnel are referenced to the mean velocity pressure at the building reference height. The external pressure coefficients are defined as follows:

$$C_{p,mean} = \frac{\bar{p} - p_0}{\frac{1}{2} \rho \bar{V}_{BH}^2} \quad E.1$$

Definitions of the terms above are described as follows:

$C_{p,mean}$	mean pressure coefficient	\bar{p}	mean pressure
ρ	air density (1.2kg/m ³)	p_0	reference static pressure
\bar{V}_{BH}			mean velocity at the building reference height

Table A1 in Appendix A presents the maximum and minimum mean and peak external pressure coefficients based on the most critical values for the range of wind directions tested, for each pressure sensor location. The corresponding wind direction that each critical value occurred at is also shown in Table A1 of Appendix A. The directional results of these coefficients are plotted in Appendix C of this report. All coefficient data presented in this report is referenced to the mean velocity pressure at the study reference height defined in Section 3.

F.3 Calculation of the Full-Scale Results

To calculate the full-scale mean hourly external pressures at the openings, the wind tunnel coefficient measurements need to be combined with information about the local wind climate. The aim of combining the wind tunnel measurements with wind climate information is to determine the expected pressure level that will occur for a given return period (mean recurrence interval). As the return period of a pressure level is directly related to the hourly probability of occurrence of this pressure level, this process may also be considered to be the determination of the pressure level for a given probability of occurrence.

The local wind climate is normally described using a statistical model, which relates wind speed to a probability of occurrence. A feature of this process is to include the impact of wind directionality which includes any local variations in wind speed or frequency with wind direction. This is important as the natural ventilation performance of a building may be highly dependent on the prevailing wind direction, and that the highest wind speed event in a given return period may not necessarily produce the highest pressure differential in the same return period.

The contribution to the probability of occurrence of a pressure level is calculated for each wind direction. These contributions are then summed over all wind directions to calculate the total probability of occurrence of this level. The pressure level is selected such that the summed probability of occurrence for this level equals the hourly probability of exceedance. A detailed description of the calculation of the pressure level and a justification for the choice of probability distribution is given by J.D. Holmes (1990).

The reference pressure is related to the reference mean wind speed by the following equation:

$$\text{Reference Pressure (Pa)} = \frac{1}{2} \rho V^2 \quad (3.1)$$

where the air density ρ is taken to be 1.2 kg/m³, which is typical for sea-level atmospheric conditions.
