1 INTRODUCTION

1.1 Background

Cardno, now Stantec Pty Ltd was engaged by TSA Management (TSA) ("the client") on behalf of NSW Health Infrastructure, to undertake an Interpretative geotechnical and contamination investigation report to determine the in-situ ground conditions, for the proposed redevelopment of Royal Prince Alfred Hospital (RPA) – Eastern Campus. The contents of this report detail the ground investigation, methodology, presentation of factual data obtained and interpretation of data appropriate for the design and construction.

The investigatory RPA Eastern Campus ("the Site") is approximately 4.5 Ha in area, located in Sydney's inner west suburb of Camperdown. The site resides under the Local Government Area (LGA) of City of Sydney.

The ground assessment comprised boreholes at nominated locations across the subject site in order to obtain relevant geotechnical and environmental information to aid detailed design for site redevelopment.

This report only presents the results of the geotechnical investigation works undertaken at RPA. A separate report has been prepared for environmental conditions encountered on site and is provided in Ref: 80022026, entitled "*Desktop Contamination Assessment with Limited Sampling*", by Cardno (NSW/ACT) Pty Ltd.

1.2 Purpose and Scope of works

The purpose of this report is to provide the client with geotechnical advice on the in-situ subsurface conditions encountered, along the proposed redevelopment works.

The scope of works undertaken are presented below:

- i) Undertaking a desktop study of existing geotechnical information for the site and surrounding areas.
- ii) Site Investigation will be carried out in accordance with AS 1726:2017 Geotechnical Investigation. The locations and depths to be undertaken following discussions with Project Civil Engineer.
- iii) Preliminary work, including preparation of a Field Work Safety and Environmental Plan (FWSEP), Safe Work Method Statements (SWMS) and site-specific paperwork and inductions as required;
- iv) Undertaking a Dial-Before-You-Dig search and check the site using an electronic services locator and GPR (ground penetrating radar).
- v) Undertake boreholes drilling as indicated on the attached plans. This includes the following
 - Drilling of four (4) boreholes (BHs) up to a depth of 5m to 8m using track and/or ute mounted geotechnical drill rig with solid flight augers and Tungsten Carbide (TC) bit.
 - Drilling of four (4) BHs to 3m into medium strength rock. Coring of the rock was carried out using NMLC diamond drilling techniques;
- vi) Undertake in-situ Standard Penetration Tests (SPT), including recovery of samples, at 1.5 m intervals in the boreholes to assess sub-surface geotechnical strength and geological material characteristics;
- vii) Reinstate borehole locations, back-filling with spoil cuttings and topping up with sand, cement grout and rapid set concrete. In instances where this method is not suitable the reinstatement shall match the existing area i.e. pavers, bitumen etc.

- viii) Survey of the investigation locations by using survey equipment Topcon GNSS Receiver to determine the ground co-ordinate marks and collar elevation, referencing to GDA 2020, Zone 56 and AHD (m) respectively;
- ix) Installation of one (1) Groundwater (GW) monitoring well in one of the drilled borehole;

Stantec

- Laboratory testing to be carried out on representative samples by Cardno NATA accredited laboratory, which may include:
 - Particle Size Distribution (AS1289.3.6.1);
 - Atterberg Limits (AS1289.3.4.1 3.3.1 3.2.1);
 - Moisture Contents (AS1289.2.1.1);

now

- California Bearing Ratio (CBR) (AS1289.6.1.1);
- Soil Aggressiveness testing (Sulphate, Chloride, Electrical Resistivity and pH testing);
- Point Load (PL) Tests; and
- Unconfined Compressive Strength (UCS).
- Acid sulphate soil (ASS) testing (covered in environmental report)

xi) Provision of a Geotechnical Report

1.3 Previous Investigation

Cardno

Douglas Partners (DP) have previously carried out a geotechnical investigation, (Ref: 99709.00 R.001.Rev0 dated 26 August 2020) for the same site which included four rock cored boreholes (BH201 – BH204). This report also included previous borehole logs carried out in 1989 (Proj Ref: 12093) and 1998 (Proj Ref: 27456) by DP.

The geotechnical information provided in DP's report also has been taken into consideration in our report. The previous borehole locations are shown on Appendix A – site plan together with cross section of subsurface profiles from previous and current investigations.

DP has carried out a total of 4 BHs (BH201 – BH024) in 2020 in the eastern campus, which were drilled to a depth of approx. 14 to 16m below surface level (BSL). Two (2) Groundwater monitoring wells at BH201 and BH202 were installed. The subsurface profile consisted of Pavement/Fill overlying Residual Clay and Ashfield shale bedrock. The bedrock comprised of very low to low strength laminite over medium to very high strength laminite/siltstone.

The geotechnical investigation carried out by DP in 1989 comprised of six boreholes (BH1 to

BH6) for Eastern Campus which were drilled up to 9.70m BSL. The subsurface profile comprised of Pavement/Fill overlying Residual Clay and Laminite. The Laminite varied from low to high strength.

The geotechnical investigation from 1998 comprised of 17 boreholes (BH1 to BH17) for the Eastern precinct. Those boreholes were drilled up to 11.45m BSL. The subsurface conditions comprised of Fill underlain by residual clay and shale and laminite bedrock. The laminate varied from low to high strength.

The interpretation of previous boreholes was carried out in accordance with Pells et al (2019) publication "Classification of Sandstone and Shales in the Sydney Region: A Forty Year Review". The interpreted subsurface profiles have been shown in the cross section provided in Appendix A – Site Plan. The borehole logs and test results are presented in Appendix E.

2 SITE DESCRIPTION

2.1 Site Description

The Royal Prince Alfred Hospital (RPA) campus is located in Sydney's inner west suburb of Camperdown. It is situated between Sydney University to the east and the residential area of Camperdown to the west. The campus is divided by Missenden Road, which runs north to south dividing the campus into two distinct portions, called East Campus and West Campus as show in Figure 2-1 below:

Figure 2-1 RPA Hospital Campus

The RPA Hospital campus (outlined in red in Figure 2-1 above) incorporates a diverse range of operations including research, education, student housing, acute quaternary health services, as well as healthcare in both private and public domains.

There is an internal road called John Hopkins Drive / Lambie Dew Drive, which loops around the Eastern hospital from North west to the South East direction.

The following figure shows the locations of RPA buildings with unique building numbers for the entire eastern and western campus.

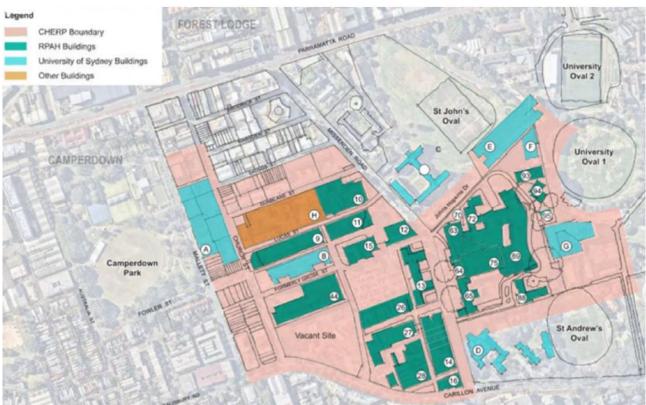

Figure 2-2 RPA Hospital Campus with building numbers

The investigatory boreholes undertaken for the hospital redevelopment are shown in Figure 2-3 below, which are also attached in **Appendix A – Site Plan**:

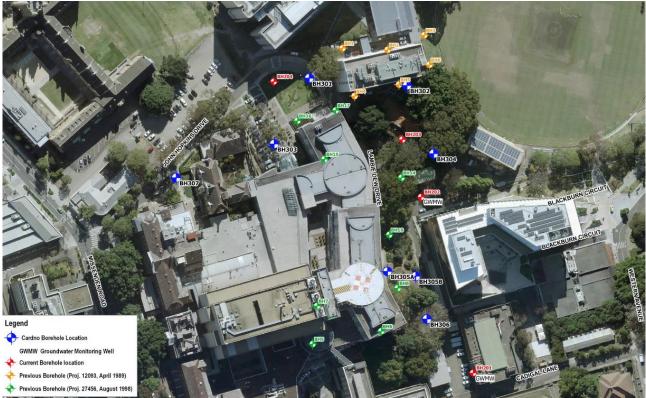

Figure 2-3 Approximate Borehole Locations

2.2 Topography and Drainage

now

Cardno

The ground surface levels generally fall towards in an easterly direction with elevation levels varying from approx. RL 29 m AHD (westerly – BH307) to RL 19 m AHD (easterly-BH 302).

Various drainage stormwater pits were present throughout the site; however, their functionality was not assessed at the time of investigation. Majority of the site consisted of hardstand pavement areas and some landscaped / garden areas were present towards the North and East of Building 89.

Based on our site observations, there are no potential risks surrounding the building that may potentially cause landslip risks and the site is not located within high erosion potential area. There is no existing landslip prone area map available for Camperdown as well which suggests that the site is not located within the known occurrence of landslip.

2.3 Regional Geology

The Sydney 1:100 000 Geological Map, Herbert C, 1983, illustrates that the subject site ins underlain by Ashfield Shale (Rwa) of Wianamatta Group from Middle Triassic period of Mesozoic era. The map shows the site is underlain by Ashfield Shale (Rwa) which is charactered as Black to dark-grey shale and laminite.

Regional geology of the site area is presented in Figure 2-4 below:

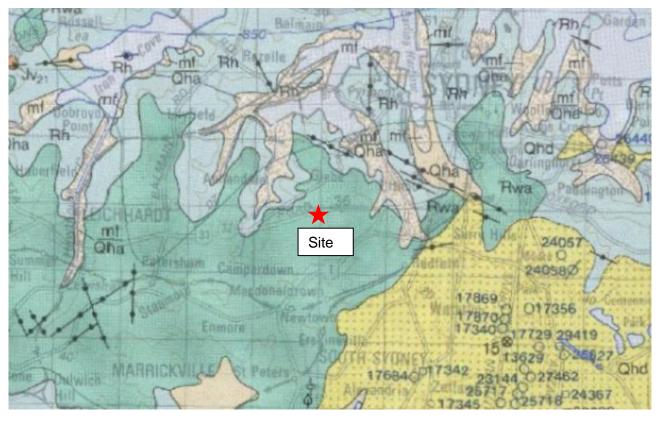

Figure 2-4 Geological Map, Herbert C., 1983, 1st Edition

3 INVESTIGATORY WORKS

now

3.1 Borehole Locations

Cardno

The ground coordinates of boreholes are listed in Table 3-1 below. At the time of investigation, all boreholes were located by survey based on nominated borehole positions outside of overhead and underlying utility services. Upon completion of works, all boreholes were picked up with Topcon GNSS Receiver, to determine the ground coordinate marks and collar elevation, referencing to GDA2020, Zone 56 and AHD (m) respectively.

ID	Easting (m)	Northing (m)	Elevation (m AHD)			
BH301	332016.065	6248761.9	22.9			
BH302	332076.300	6248757.4	19.7			
BH303	331994.419	6248721.4	27.1			
BH304	332092.740	6248715.4	21.9			
BH305A	332064.290	6248642.9	24.2			
BH305B	332081.752	6248640.0	22.6			
BH306	332088.600	6248613.6	23.2			
BH307	331934.052	6248700.6	29.8			

Table 3-1 Borehole Coordinates

3.2 Investigation Naming Convention

For fieldworks, the naming convention adopted for investigatory boreholes (BHs) was standardised in a sequential manner, since there are previously known ground investigations undertaken on the site by DP.

- i) BH3xx BH301, BH302, continuing Represents investigatory boreholes undertaken across the subject site
- BH305 was subdivided into BH305A and BH305B. BH305A was shallow borehole undertaken mainly for CBR sampling whereas BH305B was carried out to identify the subsurface profile to deeper depth targeted for eastern extension to Building 89.

3.2.1 Fieldwork Activities

Fieldwork for the investigation was carried out from 29th of November to 3rd of December 2021, comprising of the following sequence of activities;

- i) A review of Dial Before You Dig (DBYD) and on-site service search.
- ii) Drilling of eight (8) boreholes (BHs) using a track and ute mounted drill rig. Four (4) BHs were drilled up to a depth of 8m below surface level (BSL) and four (4) BHs were drilled up to 15.21m BSL;
- iii) Standard Penetration Tests (SPT) were undertaken within the soil profile at 1.50 m intervals;
- iv) Collection of disturbed soil samples for laboratory testing;
- v) Installation of one GW monitoring well at BH303 location;
- vi) Reinstatement of boreholes

All fieldworks, including logging of the subsurface profile, collection of soil samples, was undertaken by Geotechnical Engineers from Cardno. The locations of the completed geotechnical investigations are shown on the borehole location plan, attached to this report in Error! Reference s

ource not found. Appendix A – Site Plan.

Subsurface conditions encountered are summarised in Section 6 and detailed in engineering borehole logs attached in **Appendix B** together with explanatory notes. Fieldwork was carried out in accordance with Australian Standard, AS1726-2017 '*Australian Standard - Geotechnical Investigations*'.

A breakdown of fieldwork activities is presented below:

3.2.1.1 Underground Service Search

A Dial Before You Dig (DBYD) underground service search was conducted by the Cardno for the site and surrounding area prior to the fieldworks. A qualified underground service locator, Astrea cleared the borehole locations from utilities, with the use of a pipe/cable locator & transmitter and ground-penetrating radar (GPR) prior to the drilling. Hand auguring was carried out for the first 1m of subsurface profile as non-destructive digging method.

3.2.1.2 Geotechnical Drilling

Investigatory drilling boreholes (BHs) were undertaken with the use of a tracked and Ute mounted rig operated by Stratacore drilling service.

Boreholes were drilled vertically (90 degrees from the horizontal). Drilling through the soil was carried out using solid flight auger with Tungsten Carbide "TC" – bit. Deep boreholes were further advanced with NMLC coring until competent rock was reached, which ever came first. Standard penetration tests (SPT) were undertaken through the soil profile at 1.50 m intervals, proceeding from 1.5m below surface level (BSL). SPT refusal was considered where 30 blows generated less than 150mm penetration.

3.2.1.3 Standard Penetration Testing (SPT)

SPT test involves raising and dropping a 63.5kg slide hammer 760mm to drive a thick-walled sample tube through the underlying layers. The number of blows it requires to penetrate the sample tube across 150mm increments is measured until the tube has penetrated 450mm into the subsurface, or the hammer is bouncing, causing refusal (Blow counts > 25).

SPT tests were undertaken, to assist with the assessment of in-situ soil strength parameters. The tests were performed at 1.0m - 1.5m increments until refusal was achieved. SPT tests are presented in engineering logs provided in **Appendix B**.

3.3 Laboratory Testing

Samples of representative strata were recovered and returned to NATA accredited laboratory. The following tests were carried out on selected samples:

- i) Three (3) samples for atterberg limits and particle size distribution testing to aid for material classification;
- ii) Two (2) samples for California Bearing Ratio (CBR) testing to aid for pavement design thickness;
- iii) One (1) sample for shrink swell testing to aid for characteristic surface movement;
- iv) Three (3) samples to aid with strength of the selected rock cores;
- v) Three (3) samples to aid with chemical characterisation of the soils;
- vi) Four (4) samples for Uniaxial Compressive Strength (UCS) testing to aid for rock strength; and
- vii) Point load strength index tests were carried out every 1 m of recovered core where defect spacing provided enough core to carry out testing. A total of twenty (25) point load strength index tests were carried out;

The Laboratory test results for soils and rock are included in **Appendix C**. Laboratory testing was carried out in accordance with Australian Standard AS1289 'Laboratory Testing for Engineering

Purposes'.

4 PROPOSED DEVELOPMENT

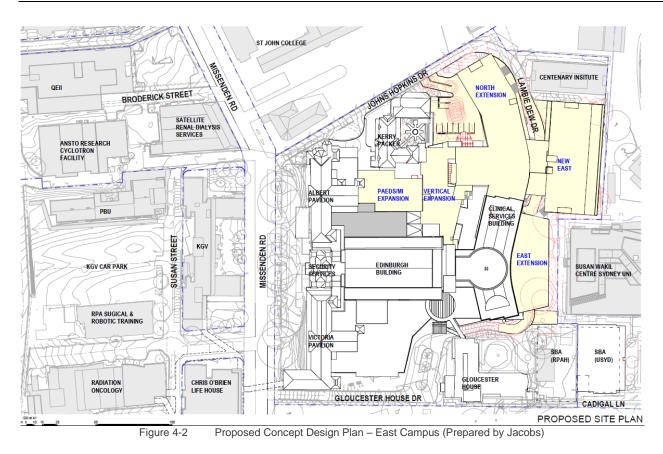

The proposed development zone is situated within the Eastern campus as shown in Figures 4-1 below and the concept design plan prepared by Jacobs (Ref: IA0251300- MW- AR- DRG-0102(1)) for Eastern Campus is shown in Figure 4-2 below. The proposed development testing zone will encompass:

- i) the building footprints of the new proposed development;
- ii) areas between the existing buildings and new proposed development;
- iii) John Hopkins Drive and Lambie Dew Drive due to potential civil works for road realignment/ enhancements and service diversions;
- iv) Gloucester House Drive due to potential civil works for new in-ground services/ services connections;
- v) existing Building 89 which may be subject to vertical expansion and refurbishment works to some levels;
- vi) New Mortuary drop off within the access lift between levels 1 and 2 of Building 89;
- vii) Relocation of the existing roller shutter door on the eastern side of the Clinical Services Building; and
- viii) some departments within some levels of existing Buildings 63, 75, 94 and 95 which may be subject to refurbishment works

Figure 4-1 Proposed Development Zone – East Campus

5 GROUND CONDITIONS ENCOUNTERED

A brief summary of the typical sub-surface conditions encountered within each investigatory locality is provided below. For full description of the sub-surface profiles encountered, reference can be made to the borehole logs presented in **Appendix B**.

5.1 Subsurface Strata

The ground conditions across the subject site were relatively uniform and resembled with the geology (Rwa – Ashfield Shale) as shown on the published map.

The subsurface profiles encountered across the site were as follows:

- > Asphaltic concrete / concrete paver, between 0.00 m and 0.40 m, overlying;
- > Fill consisting of Gravelly Sand, Silty/Sandy Clay, between 0.10 m and 3.30 m, overlying;
- > Possible residual soil, comprising of silty CLAY, between 0.15 m to 3.30 m, overlying;
- > Residual Silty CLAY, between 1.45 m to 7.00 m;
- > Bedrock, comprising of Siltstone/Laminite, between 4.10 m to 15.21 m;

The subsurface profile is summarised in Table 5-1 below, and presented in engineering logs attached in Appendix B, together with explanatory notes.

Stantec

Table 5-1 Subsurface Conditions Summary

now

Cardno

Notes:

All depths measured in metres below ground surface level (Refer to Table 4-1) at the time of the investigation. 1.

Refer to attached Soil Description, Rock Description and Glossary of Terms on Appendix B for a full list of symbols and terms. 2. 3.

Soil Classification follows United Soil Classification system (USCS).

TD = Termination Depth. 4.

R = Auger Refusal Depth 5.

6. BSL = Below Surface Level

5.2 Groundwater

Groundwater seepage was encountered at 4.50m and 6.00m BSL within BH306 during investigatory borehole drilling. A groundwater monitoring well was also installed at the BH03 location. There were two monitoring wells previously installed by DP at BH201 and BH202.

It should be noted that groundwater levels may fluctuate depending on the time of year and following periods of wet weather.

The following table shows a summary of the groundwater levels encountered and measured during the investigation:

Table 5-2	Groundwater Monitoring Result	S
-----------	-------------------------------	---

Borehole ID	Date and Time	Depth m BSL	RL m AHD
BH201	12/01/22 @1045	1.69	21.51
BH202	12/01/22 @0930	5.72	20.68
BH303	12/01/22 @0800	7.81	19.29

5.3 Laboratory testing results (Geotechnical)

5.3.1 Soil Properties and classification

A summary of the material classification testing on selected samples are presented below, in Table 5-3. Geotechnical laboratory test results have been presented in Appendix C.

Table 5-3	Soil Classification lab results summary
-----------	---

Borehole	Depth (m)	MC (%)	Gravel (%)	Sand (%)	Fines (%)	LL (%)	PL (%)	PI (%)	LS (%)
BH 302	2.0-2.50	20.4	3	8	89	54	20	34	12.5
BH 303	4.0-4.50	17.4	1	10	89	53	20	33	13.0
BH 305B	4.0-4.50	23.1	8	13	79	62	21	41	17.5

Notes:

PI: Plasticity Index

MC: Field Moisture Content LS: Linear Shrinkage

NP: Non-Plastic

5.3.2 California Bearing Ratio (CBR)

Results of CBR and Standard Maximum Dry Density (SMDD) tests on selected samples from the investigatory boreholes are summarised below in Table 5-4.

Table 5-4 **CBR** Laboratory Results

Hole ID	Depth (m BSL)	SMDD (t/m3)	OMC (%)	CBR (%)	Swell (%)
BH 305A	2.50-3.00	1.70	19.5	3.5	2.5
BH 301	0.50-1.00	1.54	25.0	5.0	1.5

Notes:

CBR testing was undertaken on remoulded specimens compacted to a target 100% standard maximum dry density with a 1. surcharge of 4.5 kg and soaked for four days. Subgrade strength is moisture and density dependent and where the existing subgrade is compacted to 100% standard compaction and moistures above OMC exist, the in situ CBR values may be less than the above tested values.

2. OMC - Optimum Moisture Content

5.3.3 Shrink Swell Test

The results of the shrink swell test are presented in Table 6-5 below.

Table 5-5 Results of Shrink Swell test

Borehole Number	Depth (m)	Shrink Swell Index %
BH307	1.00 - 1.45	2.2

5.3.4 **Uniaxial Compression Strength**

The results of uniaxial compression strength (UCS) testing on selected samples are summarised below in Table 6-6 below. The UCS and point load test results are attached in Appendix C.

Table 5-6	Uniaxial Compression Streng	th Results	
	Hole ID	Sample Depth (m BSL)	Uniaxial Compressive Strength UCS (MPa)
	BH 302	10.68-10.85	52
	BH 303	13.45-13.67	50
	BH 304	15.00-15.11	36
	BH 306	12.28-12.43	10

5.4 Laboratory testing results (Chemical)

5.4.1 Soil Aggressivity Test Results

Results of soil aggressivity tests on selected samples obtained from selected boreholes are summarised in Table 5-7 below:

LL: Liquid Limit

PL: Plastic Limit

Hole ID	Depth (m BSL)	Chloride (mg/kg)	Conductivity (µS/cm)	Hq	Resistivity (ohm.cm)	Sulphate (mg/kg)	Moisture (%)	Exposure Classification ^a (AS2159- 2009)
BH302	2.50	31	150	5.1	6800	37	17	Mild aggregoive to
BH303	3.40	<10	64	4.9	16000	17	6.6	Mild aggressive to steel and mild aggressive to
BH306	3.0	11	83	5.4	12000	<10	22	concrete

Notes: 1.

Based on AS 2159-2009 and groundwater condition mentioned above in Section 6.2.

6 GEOTECHNICAL ASSESSMENT

6.1 General

Geotechnical parameters for RPA hospital redevelopment have been developed based on available geotechnical information obtained to date for the project, published data and our experience of materials of similar nature and history on projects within Sydney region.

The design values derived are generally obtained from statistical analyses of project specific in-situ and laboratory test results. The values are considered to be representative of the properties of the material in its current condition. Where there are insufficient jn-situ or laboratory tests, empirical correlations are used.

When project specific in-situ and laboratory tests, or empirical correlations are not applicable or not available, design values are then chosen with due consideration of relevant experience from past projects and the application of engineering judgement.

6.2 Subsurface Conditions / Geology

The general ground conditions encountered on site have been discussed in Section 6 of this report. In summary the ground condition encountered are relatively similar comprising asphaltic pavement / concrete paver overlying fill, overlying residual soil and siltstone / laminite bedrock. From the borehole investigation undertaken on site, the subsurface ground profile was generally consistent with the geology maps.

6.3 Earthworks

6.3.1 Site Preparation

The following sections provide advice on preparation, formation and unsuitable materials. The relevant earthworks standards referred to as a basis for design considerations and recommendations include:

- i) AS3798-2007 'Guidelines on Earthworks for Commercial and Residential Developments'.
- ii) Safe Work Australia Excavation Work Code of Practice
- iii) Prior to bulk earthworks, the site shall be cleared of any foreign matter or unsuitable material which includes but may not be limited to the following:
 - Vegetation or organic matter including root balls of any larger trees onsite;
 - Topsoil or soil significantly affected by roots or root fibres;

- Any scattered waste or dumped materials;

now

- Uncontrolled filling which may be subject to further assessment;

Stantec

- Loose or low strength (soft to firm) soils or otherwise 'unsuitable' soils; or
- Expansive soils.

Cardno

BasedErosion and sediment control plan should be implemented before commencing any earthworks for the proposed development.

6.3.1.1 Structural Fill / Compaction Specification and Quality Control

Prior to the placement of any structural fill, the site should be proof rolled using a minimum 12 tonne roller in the presence of the geotechnical engineer. Should isolated soft/loose areas be encountered during this process, this material should be removed and replaced with suitable granular structural fill. Structural fill could comprise a select well graded granular material such as processed sandstone and road-base (DGB20). Additional filling may also be required for levelling purpose.

Depressions formed by the removal of vegetation should have all disturbed soil cleaned out and be backfilled with compacted select fill material.

To minimise the potential for post compaction volume change due to moisture content variations, any structural clay bearing fill, containing cohesive strata, should be placed in loose layers not greater than 300mm in thickness, and compacted to a minimum 98% of Standard Maximum Dry Density (SMDD) at a moisture content within 2% of standard optimum moisture content.

If the structural fill is located in landscaped areas, then the minimum density ratio can be reduced to 95% of SMDD.

Measures should be adopted to ensure that this clay fill material is not allowed to dry out prior to the placement of succeeding layers of fill and final covering with building slabs and road pavements.

It is recommended that the placement of all structural fill be inspected, tested and certified by Cardno to Level 1 requirements, during the earthworks operations to ensure that all fill is placed in a 'controlled manner', in accordance with AS3798-2007 'Guidelines on Earthworks for Commercial and Residential developments'.

Site observations and laboratory test results have indicated the presence of high plasticity silty clays in majority of areas which could be adversely affected by inclement weathered. Whilst these soils are typically of a stiff to very stiff consistency when dry, they can rapidly lose strength during wet periods. Trafficking over areas where high moisture content and low strength residual clays may not be possible without the use of bridging layers, structural fill and/or geogrids.

Conventional sediment and erosion control measures should also be implemented during the construction phase.

6.3.2 Material Management

The following general comments regarding appropriate material management shall be considered for design;

- i) Strict moisture and compaction control, with fill materials placed as close to OMC as practical while not exceeding the OMC. Over compaction shall also be avoided;
- ii) The clays would generally be suitable for general fill, and would be expected to provide a suitable subgrade for road construction; however, depending on the material utilised, a select layer and appropriate drainage would be recommended due to the swell potential;
- iii) Any oversized material should be screened prior to use as fill material.

iv) The contamination report shall also be read in conjunction to this geotechnical report for the suitability of material re-use on site.

Stantec

6.3.3 Excavation Conditions

now

D Cardno

When considering excavation at any of the sites, the findings and recommendations presented in the Contamination Assessment report should also be considered.

It is recommended that construction contractors assess the engineering logs, core photographs and rock cores to make their own assessment of excavation plant and production rates. Below recommendations are preliminary only and based on the geotechnical information across the site. Assessment of material excavatability can be based on the method published by Pettifer and Fookes (1994). The degree of excavatability of rock is based on its Point Load Index (Is50) and fracture spacing.

Excavatability categories range from easy to hard digging, through easy to hard ripping, to blasting.

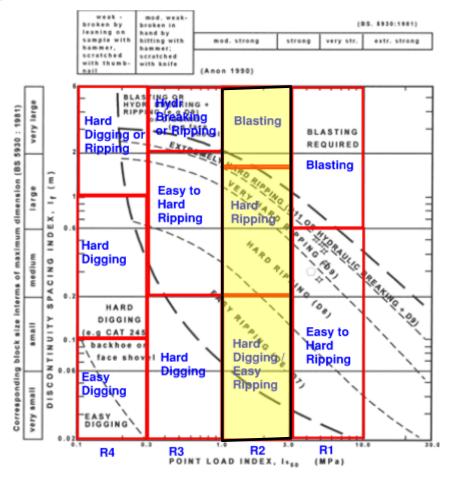

Figure 6-1 Zoning of excavatability based on Pettifer and Fookes (1994)

Examination of Figure 7-1 shows that the excavatability zones are delineated according to rock strength categories (R4-low strength, R3-medium strength, R2-high strength, R1-very high strength), and further subdivided based on the defect spacing of the rock.

Our review of the borehole logs indicates that bedrock conditions encountered were generally moderate with defect spacing in the order of 10mm – 2970mm. It is therefore expected:

- i) hard digging to easy ripping conditions in Class III to Class V Siltstone / Laminite
- ii) hard ripping to blasting in Class II Siltstone / Laminite

Large size hydraulic excavator or similar should be adequate for hard digging conditions and the use of hydraulic rock breakers / hammer in combination with Caterpillar D9 ripper or similar should be

Stantec

adequate for hard to very hard ripping conditions.

now

Where high strength rock (R2 or better) is present at the site, excavation production rates are likely to decrease with the above machinery. Where larger cuts are required the use of chemicals can be used as an alternative option for rock splitting.

6.3.4 **Open Cuts / Temporary and Permanent**

6.3.4.1 Temporary cuts

) Cardno

Where open cuts are required as part of temporary works during ground support and embankment stability work. Recommendations for temporary unsupported cuts batters (if required) are presented in the following table:

Table 6-1 Cut Batter Recommendations

Geotechnical profile	Temporary Batter (Horizontal to Vertical Ratio)	
Fill	2H:1V	
Residual Soil	1.5H:1V	
Class V / IV Siltstone / Laminite	1V:1H	
Class III / II Siltstone / Laminite	Refer to Note (g)	

Notes:

Table 6-1 applies to temporary unsupported cut batters only, for a period of no greater than 3 months once constructed 2. Temporary batters apply to cuts no greater than 1.50m in vertical height. Where deeper cuts are proposed for each

- stratum, further geotechnical designed support or retention systems may be required. 3. Excavations in soil have assumed no groundwater table has been encountered;
- 4. The ground surface at the crest of the excavation is horizontal;

There is no surcharge at the crest of the excavation for a distance equal to the depth of the excavation;
 All cuts are protected from erosion.

7. Temporary sub-vertical excavations in Sandstone/Siltstone (Class III - II = medium strength or better bedrock) may be considered appropriate (where encountered), upon inspection and approval by a Geotechnical Consultant.

6.3.4.2 Permanent cuts

Permanent cuts have not been fully identified at this stage, due to the unknown locality and depth of proposed cuts. However, it is considered where the training facility is proposed, deep cuts are envisaged as part of permanent works, where the following measures would potentially be required.

Table 6-2 Permanent Options

Geotechnical Profile	Permanent Options	Additional Comments
Fill	 i) Regrade batter – potentially strip and replace ii) Soil nail and shotcrete 	Due to variability of material in fill stratum, the existing fill where cuts are required, the fill recommended to be removed and replaced with controlled fill.
Residual Soils	iii) Regrade batter slopeiv) Soil nail and shotcrete	Not much residual soil encountered across subject site
Class II to V Siltstone / Laminite	 v) Regrade batter vi) Scaling, block removal and reprofiling vii) Rock / spot bolting viii) Rock fall netting ix) Catch fence and ditches 	Requires geotechnical input / site observations during top down excavation works to determine extend of stabilization options required

Excavation Support / Shoring 6.3.5

Where deep excavations are to be proposed, earth pressures for shoring support are provided in Table 6-4 material strength parameters. The options for the lateral support that may be considered are tabulated below:

Table 6-3 Recommendation for Shoring Options

Cardno now

Wall Type	Advantages	Disadvantages	Additional Comments
Open Cut excavation	Simple / Cheap Option	Dependent on batter slope space	 i) Consideration of groundwater table required. ii) Base and slope instability and dewatering to be assessed.
Sheet pile wall	 i) Provides an economic embedded wall ii) No arising's to be removed iii) Suitable as a water retaining system 	 iv) Potential declutching in coarse grained soil v) Difficult to impose installation where shallow rock exists 	 vi) Use of tie back anchors (soil strength and space considerations). Cantilever sheet piles to be evaluated. Groundwater table and tanking to be considered.
Secant Piles	 i) A permanent water retaining wall ii) Installed using standard piling plant with high torque rigs 	Depth is limited by the vertical tolerance, which may determine the depth of secanting	 iii) Use of tie back anchors (soil strength and space iv) considerations). Cantilever option to be evaluated. v) Groundwater table and tanking to be considered.
Contiguous Piles	The cheapest form of concrete piled wall	 i) Not a water retaining solution ii) Not a permanent solution in any soil due to gaps between piles unless structural face is applied. 	The presence of a shallow groundwater table makes this option unlikely.

Stantec

Considering the above options, pros and cons, the following recommendations are given.

- i) Where excavation is not along another property, use open excavation technique.
- ii) Where excavation is along another property the following two options should be considered.
 Use a tied back sheet pile wall.
 - Use an internally braced sheet pile wall where structures sensitive to settlement / horizontal movement are located within 15m from the excavation. Elsewhere, use cantilevered sheet pile walls with provision for remedial works on the adjacent property.
 - Alternative to the above, install secant piles and use them as part of the permanent basement wall.

6.3.6 Groundwater Conditions

Due to the presence of shallow groundwater level, significant groundwater inflow is likely and is likely to vary with rainfall events as well. Some seepage into excavations is likely to occur through fissures in the residual soil, at the soil / rock interface and from joints and bedding planes in the rock. The permeability of the siltstone/sandstone rock mass is considered to be generally relatively low, although localised inflows could be high through discrete rock defects.

Further detailed investigations and groundwater modelling will be required to predict seepage rates and drawdown in the short and long term, if any basement levels are proposed.

6.3.7 Vibrations

The excavation will have to be carried out in close proximity to other hospital buildings, hence use of impact hammers may result in vibrations that could affect adjacent structures. A rock saw could be used to reduce the lateral transfer of vibrations.

For general guideline purposes, induced vibrations in structures adjacent to the excavation should not exceed a Peak Particle Velocity (PPV) of 5mm/sec for structures in good condition, or 2mm/sec for structures in poor condition or heritage structures. If vibrations in adjacent structures exceed these PPV's or if vibrations appear excessive, this office should be contacted immediately for further advice.

6.4 Aggressiveness Classification

now

In accordance with AS3600 (2018), exposure classification for concrete 'A2' for the subsurface materials across the investigated areas. Future concrete structures should be designed in accordance with the concrete cover specifications in AS 3600 (2018) for an exposure classification of 'A2'.

6.5 Site Classification

Cardno

It has been assessed that there is more than 400mm depth of fill across the majority of the subject site, which in the absence of any construction records should be considered as '*uncontrolled*' in accordance with AS2870-2011 "*Design of Footings and Slabs for Residential Construction*. Therefore, the site is classified as Class "P".

However, if the site is prepared in accordance with Section 6.3 of this report, the site can be reclassified based on the shrink swell index (I_{ss}) results. The shrink swell test on natural clay collected from BH307 resulted in 2.2% I_{ss} and three shrink swell tests carried out by Douglas Partner gave I_{ss} in the range of 1.7 - 2.9%. With consideration of these shrink swell indices and the soil profile, the site can be reclassified as moderately reactive clay site (Class 'M1'), which may experience moderate ground movement from moisture changes with a characteristic surface movement of 20 - 40mm.

6.6 Seismic Classification

Based on the subsurface conditions encountered across the site, the site sub-soil Class C_e (shallow soil) can be assigned in accordance with AS1170 - 2007 *"Structural Design Actions, Part 4: Earthquake Actions in Australia"*. A hazard factor (Z) of 0.08 can be applied for sites in Sydney.

6.7 Geotechnical Parameters

Based on the borehole logs and the results of laboratory tests, geotechnical design parameters are inferred and presented to assist with geotechnical design.

6.7.1 Soil Classification

No geotechnical parameters have been assigned to manmade fill layers due to potential variability. Relative density/consistency of natural granular/cohesive layers, if any, shall be assessed based on SPT N values. All manmade (i.e. fill) layers are recommended to be considered loose (for granular soils), as presented below;

Material	γ (kN/m ³)	C _u (kPa)	c' (kPa)	φ' (°)	E' (MPa)		Ka	K _p
Fill	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A
CLAY (Firm)	18	25	0	24	4	0.35	0.42	2.37
CLAY (Stiff)	19	50	2	26	8	0.35	0.39	2.56
CLAY (Very Stiff)	20	100	5	28	15	0.35	0.36	2.77

Table 6-4 Material Strength Parameters

Material	γ (kN/m³)	C _u (kPa)	c' (kPa)	φ' (°)	E' (MPa)		Ka	K _p
CLAY (Hard)	21	200	10	28	30	0.3	0.36	2.77
Siltstone / Laminite Class V	22	-	10	29	100	0.3	0.34	2.88
Siltstone / Laminite Class IV	23	-	25	30	300	0.3	0.33	3.00
Siltstone / Laminite Class III	23	-	100	32	600	0.2	-	-
Siltstone / Laminite Class II	24	-	300	34	1200	0.2	-	-

Notes: γ : Unit Weight

c_u: Undrained Shear Strength

c': Drained Shear Strength

E': Elastic Modulus

φ': Internal Friction Angle

 ν ': Poisson's ratio

K_a: Active Earth Pressure

K_p: Passive Earth Pressure N/A = No geotechnical parameters have been assigned to topsoil layers due to potential variability.

6.7.2 **Rock Classification**

The classification of sandstone and shale rock encountered on site is summarised in Table 6-5 which are extracted from current Pells et al (2019) publication "Classification of Sandstone and Shales in the Sydney Region: A Forty Year Review".

Table 6-5 Rock Mass Classification System - Shale - Pells et al (2019)

Rock Mass Classification	Unconfined Compressive Strength qս (MPa)	Defect Spacing	Allowable Seams
I	>16	>600	<2%
II	>7	>200	<4%
III	>2	>60	<8%
IV	>1	>20	<25%
V	>1	N/A	N/A

Considering the classification system, and UCS and point load testing, the rock classification for each borehole is summarised in the Table 6-6 below.

Table 6-6	Classification of Rock at Borehole Locations

BH ID	Depth from BSL (m)	RL Depth (m AHD)	Thickness (m)	Rock Classification
BH301	4.50 - 7.90	18.496-15.096	3.4	Siltstone Class V
	4.10 - 7.70	15.596-11.996	3.6	Siltstone Class V
BH302	7.70 – 10.40	11.996-9.296	2.7	Laminite Class III
	10.40 – 14.36	9.296-5.336	3.96	Laminite Class II
	4.70 – 10.00	22.398-17.098	5.3	Siltstone Class V
BH303	10.00 – 11.50	17.098-15.598	1.5	Siltstone Class III
	11.50 – 14.00	15.598-13.098	2.5	Siltstone / Laminite Class II
PLI204	5.20 – 12.26	16.673-9.613	7.06	Siltstone Class V
BH304	12.26 – 15.21	9.673-6.663	3.01	Siltstone Class III
BH305B	7.00 - 8.00	15.568-14.568	1.0	Siltstone Class V
	6.40 - 9.20	16.765-13.965	2.8	Siltstone Class V
BH306	9.20 - 11.00	13.965-12.165	1.8	Siltstone / Laminite Class
	11.00 – 14.97	12.165-8.195	3.97	Laminite Class II
BH307	5.30 - 5.50	24.518-24.318	0.2	Siltstone Class V

Note:

The above classification considers rock substance strength, defect spacing and allowable seams as required by Pells et al (2019). Thereby, a portion of rock mass not meeting an upper class is placed at the next lower class where all three factors are satisfied. A strata of rock is subjected to all three factors in general and combining thin layers of different class into a thick stratum using engineering judgement. The Designer shall review the borehole logs and core photographs to assess the potential impacts of thin layers combined in thicker layers. This is particularly true for end bearing piles which shall be checked not to be adversely impacted by weak/ highly fractured bands of rock below the designed pile toe level.

6.8 Foundation Options

Both shallow and deep options of foundations could be adopted for the proposed development. Parameters for both shallow and deep footing options are provided below;

6.8.1 Shallow / Pad Footings

Due to the unknown loads and footing systems, no specified allowable bearing capacities can be determined at this time. Once specific loadings have been ascertained, Cardno can assist to optimise the footing size and depth to suit the loading on the founding material. Bearing capacity of footings in soil needs to be subjected to geotechnical checking considering footing size, depth, slope (ground surface and/or footing base) and loadings (i.e. bearing capacity is not a soil property but is dependent of footing size, depth, slope and loadings). A footing subjected to pull out forces should be further geotechnical assessment in addition to bearing capacity, overturning and sliding. Conventional shallow footings designed in accordance with engineering principles and nominally embedded 0.5m into the design founding material, may be proportioned on the following ultimate end-bearing pressures, summarised in Table 7-7 below:

Founding Material	Area (m)	Ultimate Bearing Capacity (kPa)
CLAY - Stiff	1 x1	300
CLAY - Very Stiff	1 x1	500
CLAY - Hard	1 ×1	750
Siltstone / Laminite Class V	1 x1	850

 Table 6-7
 Shallow / Pad Footing Design Parameters

Note:

1. Ultimate bearing capacity tabulated above assuming eccentricity of 1/6 x footing width.

2. Horizontal ground is assumed

3. Consideration of Section 6.3 should be considered, prior to selection of founding level.

4. The settlement for shallow footings depends upon the loading conditions, footing size and foundation material, but it should be

less than 1% of the footing width if proportioned on the basis of above parameters.

5. A minimum geotechnical strength reduction factor Øg of 0.4 can be applied for the allowable design values.

6.8.2 Deep Foundations

The proposed structures are recommended to be founded on piles that transfer the column loads to more suitable founding strata at depth below the sites. The type of pile will depend on the specific ground and groundwater conditions and relative cost. For the purposes of pile design, the parameters shown in Table 6-8 may be used. However, if bored piles are adopted, the base of the piles must be inspected during construction to ensure that material of adequate capacity supports each pile.

Table 6-8Pile Design Parameters	(Based on Pells 2019)
---------------------------------	-----------------------

Class	Serviceability End bearing MPa	Ultimate Shaft adhesion ¹ kPa	Typical Efield MPa
Siltstone / Laminite Class II	5	600	1200
Siltstone / Laminite Class III	3.5	350	600
Siltstone / Laminite Class IV	1	150	300
Siltstone / Laminite Class V	0.7	50	100

Note:

1. Clean Sockets for roughness category R2 or better is required.

2. Horizontal ground is assumed

3. The settlement for shallow footings depends upon the loading conditions, footing size and foundation material, but it should be less than 1% of the footing width if proportioned on the basis of above parameters

Further Discussions for Pile Footings

now

Cardno

- i) Where the design is dependent upon end bearing resistance, piles must extend at least 0.5m into the founding stratum to develop full design end bearing.
- ii) The base of the piles must be inspected during construction to ensure that material of adequate capacity supports each pile.

Stantec

- iii) In accordance with the requirements of AS2159-2009, a geotechnical reduction factor is to be applied to the ultimate geotechnical strength to obtain the design geotechnical strength. We have determined that an average risk rating ARR=3.07 (corresponding to a moderate overall risk category) and a geotechnical reduction factor $\phi g = 0.52$ can be adopted for this project. This is based on the following assumptions:
 - Detailed level of construction control is required with professional geotechnical supervision, construction processes that are well established and relatively straightforward;
 - No performance monitoring of the supported structure during and after construction is proposed;
 - Table 6-9 below gives an option table for the proposed deep foundations that can be adopted across the subject site, discussion and comments being noted;

Wall Type	Advantages	Disadvantages
Bored Piles	i) Quiet / No Vibrationii) Greater lengths can be installed	 iii) Requires the use of liners and possible slurry. iv) Requires additional plant (cranes, etc)
CFA Piles	 i) Low Noise / vibration ii) No need for casing due to sloughing/seepage iii) Faster productivity than bored piles 	 iv) A higher waste of concrete than traditional bored piles v) Requires additional plant (Cranes, etc)

Table 6-9 Deep Foundation Options

6.9 Ground Anchors

Where required, the use of ground anchor is suggested to provide lateral restraint on the boundary soldier wall. Such ground anchors should be declined below the horizontal to allow anchorage into the stronger materials at depth. It should be noted that installation of ground anchors beyond the site boundaries will require permission to be obtained from relevant authorities and adjacent property owners. The design of temporary ground anchors for the support of pile wall systems may be carried out using the following parameters provide in Table 6-10 below:

Table 6-10 Allowable Bond Stresses for Anchor Design

	5
Material	Allowable Bond Stress ¹ (kPa)
Siltstone / Laminite Class III	300
Siltstone / Laminite Class IV	150
Siltstone / Laminite Class V	50

Note:

1. The anchors should have a minimum bond length of 3m. The anchor free length is determined to have the bond length behind the plane of failure starting from the bulk excavation level. The horizontal inclination of the plane of failure is considered to be 45 degrees.

2. All anchors should be proof tested to 1.3 times the working load under the direction of an experienced engineer.

6.10 Pavement Design Evaluation

now

Cardno

As presented in Table 6-4, laboratory soaked CBR tests indicates a subgrade swell of between 1.5% to 2.5% considered as moderately expansive soil. Test result for the specimens indicate CBR values of 3.5 % and 5.0%. A review of SPT testing indicates that the residual subgrade material, generally consisted of stiff to hard clay.

Stantec

Based on the previous results reported by DP on clayey fill and natural clay, CBR value ranged from 2 - 7%.

Taken into consideration of existing and previous CBR test results, a design CBR of 2% can be adopted for pavement design of Lambie Dew Drive.

7 CONSTRUCTION INSPECTION

It is recommended that placement of all structural fill and footing excavations be inspected, tested and certified where necessary, by a suitably qualified geotechnical engineer to ensure recommendations made in this report have been addressed. Should subsurface conditions other than those described in this report be encountered, Cardno should be consulted immediately and appropriate modifications developed and implemented if necessary.

8 CONCLUSION AND RECOMMENDATIONS

The following provides a summary of the conclusions and recommendations with regard to the geotechnical investigation that was undertaken for RPA Eastern Campus. The following conclusions can be drawn from Cardno's geotechnical investigation works undertaken, however the proceeding sections of this report should be read for a full description of the conclusions:

- i) Geotechnical investigatory works were undertaken for the proposed redevelopment of RPA Hospital Eastern Campus;
- ii) Investigatory works comprised of drilling eight (8) boreholes. Four (4) BHs were drilled up to a depth of 8m below surface level (BSL) and four (4) BHs were drilled up to 15.21m BSL;
- iii) Standard Penetration Tests (SPT) were undertaken within the soil profile at 1.50 m intervals;
- iv) Installation of one GW monitoring well at BH303 location;
- v) The subsurface condition encountered across the site were relatively uniform across the site. The ground profile generally comprised of a pavement/fill overlying residual soil and siltstone/laminate bedrock.
- vi) Investigatory laboratory test results can be found in section 6 of this report along with laboratory test certificated in Appendix C.
- vii) Recommendations on earthworks and foundation options are discussed in Section 7.

10 CLOSURE

We appreciate the opportunity to work collaboratively with you on this project. Our team looks forward to

bringing our high level of expertise to deliver successful outcomes in your future projects. Your attention is drawn to the appended document titled "*Important Information about this Geotechnical Report*". This document is intended to clarify to the reader what the realistic expectations of this report should be, and what is the correct use of the document. Misinterpretation of geotechnical information presents significant risk to projects: The document includes a discussion on general limitations of geotechnical services, which by nature, are based extensively on opinion and judgement.

The statements included in this document are not intended to be exculpatory clauses or to reduce the general responsibility accepted by Cardno, but rather to identify where Cardno and our Client's responsibilities lie. The statements ensure that all parties that may rely on the report are aware of their respective responsibilities.

For further enquiries, please do not hesitate to contact Cardno on the information supplied.

ENGINEERING LOGS

Explanatory Notes

The methods of description and classification of soils and rocks used in this report are based on Australian Standard AS1726-2017 Geotechnical Site Investigations. Material descriptions are deduced from field observation or engineering examination, and may be appended or confirmed by in situ or laboratory testing. The information is dependent on the scope of investigation, the extent of sampling and testing, and the inherent variability of the conditions encountered.

Subsurface investigation may be conducted by one or a combination of the following methods.

Method			
Test Pitting: exc	avation/trench		
BH	Backhoe bucket		
EX	Excavator bucket		
R	Ripper		
Н	Hydraulic Hammer		
Х	Existing excavation		
Ν	Natural exposure		
Manual drilling: I	hand operated tools		
HA	Hand Auger		
Continuous sam	ple drilling		
PT	Push tube		
PS	Percussion sampling		
SON	Sonic drilling		
Hammer drilling			
AH	Air hammer		
AT	Air track		
Spiral flight auge	Spiral flight auger drilling		
AS	Auger screwing		
AD/V	Continuous flight auger: V-bit		
AD/T	Continuous spiral flight auger: TC-Bit		
HFA	Continuous hollow flight auger		
Rotary non-core	drilling		
WB	Washbore drilling		
RR	Rock roller		
Rotary core drilling			
PQ	85mm core (wire line core barrel)		
HQ	63.5mm core (wire line core barrel)		
NMLC	51.94mm core (conventional core barrel)		
NQ	47.6mm core (wire line core barrel)		
DT	Diatube (concrete coring)		

Sampling is conducted to facilitate further assessment of selected materials encountered.

Sampling method Soil sampling В Bulk disturbed sample D Disturbed sample С Core sample ES Environmental soil sample SPT Standard Penetration Test sample U Thin wall tube 'undisturbed' sample Water sampling WS Environmental water sample

Field testing may be conducted as a means of assessment of the in situ conditions of materials.

Field	testing

SPT	Standard Penetration Test		
HP/PP	Hand/Pocket Penetrometer		
Dynamic Penetrometers (blows per noted increment)			
	DCP	Dynamic Cone Penetrometer	
	PSP	Perth Sand Penetrometer	
MC	Moisture Content		
VS	Vane Shear		
PBT	Plate Bearing Test		
IMP	Borehole Impression Test		
PID	Photo Ionization Detector		

If encountered, refusal (R), virtual refusal (VR) or hammer bouncing (HB) of penetrometers may be noted.

The quality of the rock can be assessed by the degree of natural defects/fractures and the following.

Rock q	Rock quality description		
TCR	Total Core Recovery (%)		
	(length of core recovered divided by the length of core run)		
RQD	Rock Quality Designation (%)		
	(sum of axial lengths of core greater than 100mm long divided by the length of core run)		

Notes on groundwater conditions encountered may include.

Groundwater	
Not Encountered	Excavation is dry in the short term
Not Observed	Water level observation not possible
Seepage	Water seeping into hole
Inflow	Water flowing/flooding into hole

Perched groundwater may result in a misleading indication of the depth to the true water table. Groundwater levels are also likely to fluctuate with variations in climatic and site conditions.

Notes on the stability of excavations may include.

Excavation conditions		
Stable	No obvious/gross short term instability noted	
Spalling	Material falling into excavation (minor/major)	
Unstable	Collapse of the majority, or one or more face of the excavation	

Explanatory Notes: General Soil Description

The methods of description and classification of soils used in this report are based on Australian Standard AS1726-2017 Geotechnical Site Investigations. In practice, a material is described as a soil if it can be remoulded by hand in its field condition or in water. The dominant component is shown in upper case, with secondary components in lower case. In general descriptions cover: soil type, plasticity or particle size/shape, colour, strength or density, moisture and inclusions.

In general, soil types are classified according to the dominant particle on the basis of the following particle sizes.

Soil Classific	ation	Particle Size (mm)
CLAY		< 0.002
SILT		0.002 0.075
SAND	fine	0.075 to 0.21
	medium	0.21 to 0.6
	coarse	0.6 to 2.36
GRAVEL	fine	2.36 to 6.7
	medium	6.7 to 19
	coarse	19 to 63
COBBLES		63 to 200
BOULDERS		> 200

Soil types may be qualified by the presence of minor components on the basis of field examination methods and/or the soil grading.

Terminology	In coarse	In fine soils	
reminology	% fines	% coarse	% coarse
Trace	≤5	≤15	≤15
With	>5, ≤12	>15, ≤30	>15, ≤30

The strength of cohesive soils is classified by engineering assessment or field/lab testing as follows.

Strength	Symbol	Undrained shear strength
Very Soft	VS	≤12kPa
Soft	S	12kPa to ≤25kPa
Firm	F	25kPa to ≤50kPa
Stiff	St	50kPa to ≤100kPa
Very Stiff	VSt	100kPa to ≤200kPa
Hard	н	>200kPa

Cohesionless soils are classified on the basis of relative density as follows.

Relative Density	Symbol	Density Index
Very Loose	VL	<15%
Loose	L	15% to ≤35%
Medium Dense	MD	35% to ≤65%
Dense	D	65% to ≤85%
Very Dense	VD	>85%

The plasticity of cohesive soils is defined by the Liquid Limit (LL) as follows.

Plasticity	Silt LL	Clay LL
Low plasticity	≤ 35%	≤ 35%
Medium plasticity	N/A	> 35% ≤ 50%
High plasticity	> 50%	> 50%

The moisture condition of soil (w) is described by appearance and feel and may be described in relation to the Plastic Limit (PL), Liquid Limit (LL) or Optimum Moisture Content (OMC).

	ire condition and description
Dry	Cohesive soils: hard, friable, dry of plastic limit. Granular soils: cohesionless and free-running
Moist	Cool feel and darkened colour: Cohesive soils can be moulded. Granular soils tend to cohere
Wet	Cool feel and darkened colour: Cohesive soils usually weakened and free water forms when handling. Granular soils tend to cohere

The structure of the soil may be described as follows.

Zoning	Description
Layer	Continuous across exposure or sample
Lens	Discontinuous layer (lenticular shape)
Pocket	Irregular inclusion of different material

The structure of soil layers may include: defects such as softened zones, fissures, cracks, joints and root-holes; and coarse grained soils may be described as strongly or weakly cemented.

The soil origin may also be noted if possible to deduce.

Soil origin a	Soil origin and description			
Fill	Anthropogenic deposits or disturbed material			
Topsoil	Zone of soil affected by roots and root fibres			
Peat	Significantly organic soils			
Colluvial	Transported down slopes by gravity/water			
Aeolian	Transported and deposited by wind			
Alluvial	Deposited by rivers			
Estuarine	Deposited in coastal estuaries			
Lacustrine	Deposited in freshwater lakes			
Marine	Deposits in marine environments			
Residual soil	Soil formed by in situ weathering of rock, with no structure/fabric of parent rock evident			
Extremely weathered material	Formed by in situ weathering of geological formations, with the structure/fabric of parent rock intact but with soil strength properties			

The origin of the soil generally cannot be deduced solely on the appearance of the material and the inference may be supplemented by further geological evidence or other field observation. Where there is doubt, the terms 'possibly' or 'probably' may be used

Explanatory Notes: General Rock Description

The methods of description and classification of rocks used in this report are based on Australian Standard AS1726-2017 Geotechnical Site Investigations. In practice, if a material cannot be remoulded by hand in its field condition or in water, it is described as a rock. In general, descriptions cover: rock type, grain size, structure, colour, degree of weathering, strength, minor components or inclusions, and where applicable, the defect types, shape, roughness and coating/infill.

Rock types are generally described according to the predominant grain or crystal size, and in groups for each rock type as follows.

Rock type	Groups
Sedimentary	Deposited, carbonate (porous or non), volcanic ejection
Igneous	Felsic (much quartz, pale), Intermediate, or mafic (little quartz, dark)
Metamorphic	Foliated or non-foliated
Duricrust	Cementing minerology (iron oxides or hydroxides, silica, calcium carbonate, gypsum)

Reference should be made to AS1726 for details of the rock types and methods of classification.

The classification of rock weathering is described based on definitions in AS1726 and summarised as follows.

Term and symbol		Definition	
Residual Soil	RS	Soil developed on rock with the mass structure and substance of the parent rock no longer evident	
Extremely weathered	XW	Weathered to such an extent that the rock has 'soil-like' properties. Mass structure and substance still evident	
Distinctly weathered	DW	The strength is usually changed and may be highly discoloured. Porosity may be increased by leaching, or decreased due to deposition in pores. May be distinguished into MW (Moderately Weathered) and HW (Highly Weathered).	
Slightly weathered	SW	Slightly discoloured; little or no change of strength from fresh rock	
Fresh Rock	FR	The rock shows no sign of decomposition or staining	

The rock material strength can be defined based on the point load index as follows.

Term and symbol		Point Load Index I₅50 (MPa)	
Very Low	VL	0.03 to 0.1	
Low	L	0.1 to 0.3	
Medium	Μ	0.3 to 1.0	
High	Н	1.0 to 3	
Very High	VH	3 to 10	
Extremely High	EH	> 10	

It is important to note that the rock material strength as above is distinct from the rock mass strength which can be significantly weaker due to the effect of defects. A preliminary assessment of rock strength may be made using the field guide detailed in AS1726, and this is conducted in the absence of point load testing.

The defect spacing measured normal to defects of the same set or bedding, is described as follows.

Definition	Defect Spacing (mm)
Thinly laminated	< 6
Laminated	6 to 20
Very thinly bedded	20 to 60
Thinly bedded	60 to 200
Medium bedded	200 to 600
Thickly bedded	600 to 2000
Very thickly bedded	> 2000

Terms for describing rock and defects are as follows.

Defect Terms			
Joint	JT	Sheared zone	SZ
Bedding Parting	BP	Seam	SM
Foliation	FL	Vein	VN
Cleavage	CL	Drill Lift	DL
Crushed Seam	CS	Handling Break	HB
Fracture Zone	FZ	Drilling Break	DB

The shape and roughness of defects in the rock mass are described using the following terms.

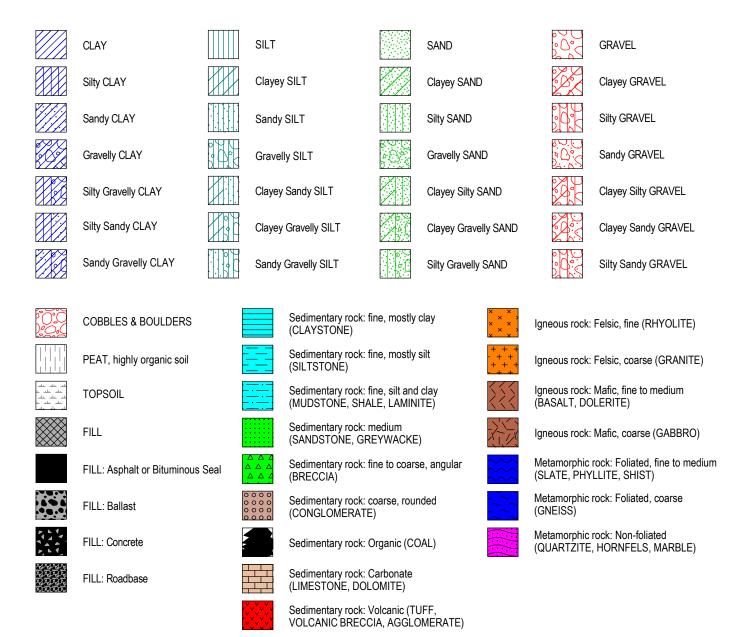

Planarity		Roughness	
Planar	PR	Very Rough	VR
Curved	CU	Rough	RF
Undulose	UN	Smooth	S
Irregular	IR	Slickensided	SL
Stepped	ST	Polished	POL
Discontinuous	DIS		

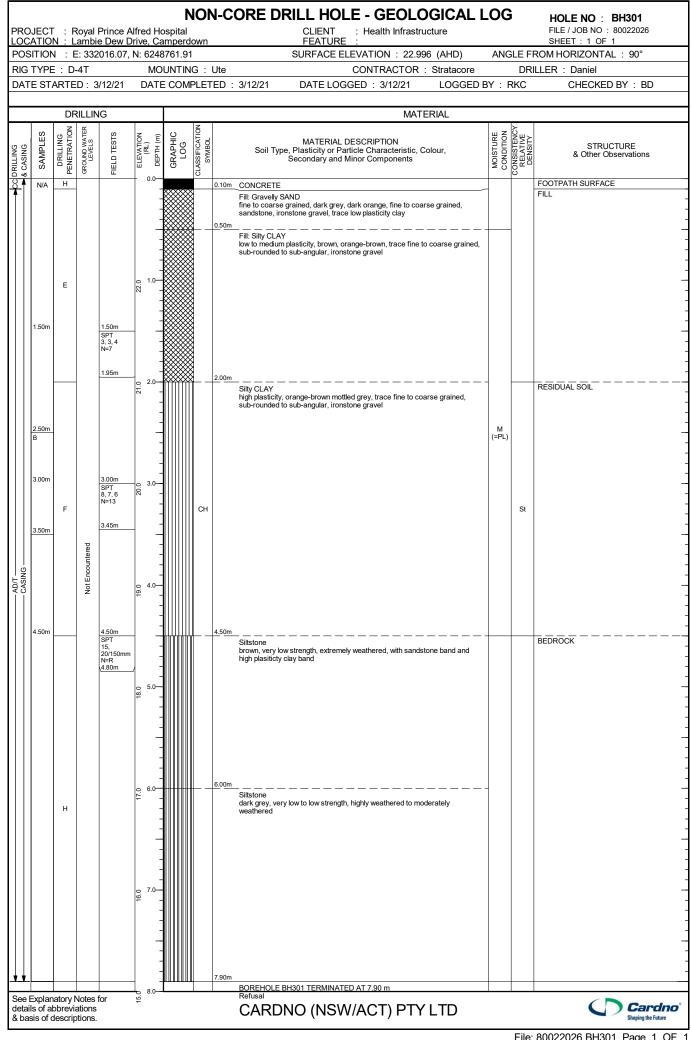

The coating or infill associated with defects in the rock mass are described as follows.

Infill and Coating		
Clean	CN	
Stained	SN	
Carbonaceous	Х	
Minerals	MU	Unidentified mineral
	MS	Secondary mineral
	KT	Chlorite
	CA	Calcite
	Fe	Iron Oxide
	Qz	Quartz
Veneer	VNR	Thin or patchy coating
Coating	СТ	Infill up to 1mm

CERTIFICATE OF ANALYSIS 247251

Client Details	
Client	Douglas Partners Pty Ltd
Attention	Peter Valenti
Address	96 Hermitage Rd, West Ryde, NSW, 2114

Sample Details	
Your Reference	99709.00, RPA Hospital Redevelopment
Number of Samples	2 Soil
Date samples received	17/07/2020
Date completed instructions received	17/07/2020

Analysis Details

Please refer to the following pages for results, methodology summary and quality control data.

Samples were analysed as received from the client. Results relate specifically to the samples as received.

Results are reported on a dry weight basis for solids and on an as received basis for other matrices.

Please refer to the last page of this report for any comments relating to the results.

Report Details	
Date results requested by	24/07/2020
Date of Issue	24/07/2020
NATA Accreditation Number 290	1. This document shall not be reproduced except in full.
Accredited for compliance with I	SO/IEC 17025 - Testing. Tests not covered by NATA are denoted with *

<u>Results Approved By</u> Priya Samarawickrama, Senior Chemist

Authorised By

Nancy Zhang, Laboratory Manager

Method ID	Methodology Summary
Inorg-001	pH - Measured using pH meter and electrode in accordance with APHA latest edition, 4500-H+. Please note that the results for water analyses are indicative only, as analysis outside of the APHA storage times.
Inorg-002	Conductivity and Salinity - measured using a conductivity cell at 25°C in accordance with APHA latest edition 2510 and Rayment & Lyons.
Inorg-081	Anions - a range of Anions are determined by Ion Chromatography, in accordance with APHA latest edition, 4110-B. Waters samples are filtered on receipt prior to analysis. Alternatively determined by colourimetry/turbidity using Discrete Analyser.

Quality Control Definitions										
Blank	This is the component of the analytical signal which is not derived from the sample but from reagents, glassware etc, can be determined by processing solvents and reagents in exactly the same manner as for samples.									
Duplicate	This is the complete duplicate analysis of a sample from the process batch. If possible, the sample selected should be one where the analyte concentration is easily measurable.									
Matrix Spike	A portion of the sample is spiked with a known concentration of target analyte. The purpose of the matrix spike is to monitor the performance of the analytical method used and to determine whether matrix interferences exist.									
LCS (Laboratory Control Sample)	This comprises either a standard reference material or a control matrix (such as a blank sand or water) fortified with analytes representative of the analyte class. It is simply a check sample.									
Surrogate Spike	Surrogates are known additions to each sample, blank, matrix spike and LCS in a batch, of compounds which are similar to the analyte of interest, however are not expected to be found in real samples.									

Australian Drinking Water Guidelines recommend that Thermotolerant Coliform, Faecal Enterococci, & E.Coli levels are less than 1cfu/100mL. The recommended maximums are taken from "Australian Drinking Water Guidelines", published by NHMRC & ARMC 2011.

The recommended maximums for analytes in urine are taken from "2018 TLVs and BEIs", as published by ACGIH (where available). Limit provided for Nickel is a precautionary guideline as per Position Paper prepared by AIOH Exposure Standards Committee, 2016.

Guideline limits for Rinse Water Quality reported as per analytical requirements and specifications of AS 4187, Amdt 2 2019, Table 7.2

Laboratory Acceptance Criteria

Duplicate sample and matrix spike recoveries may not be reported on smaller jobs, however, were analysed at a frequency to meet or exceed NEPM requirements. All samples are tested in batches of 20. The duplicate sample RPD and matrix spike recoveries for the batch were within the laboratory acceptance criteria.

Filters, swabs, wipes, tubes and badges will not have duplicate data as the whole sample is generally extracted during sample extraction.

Spikes for Physical and Aggregate Tests are not applicable.

For VOCs in water samples, three vials are required for duplicate or spike analysis.

Duplicates: >10xPQL - RPD acceptance criteria will vary depending on the analytes and the analytical techniques but is typically in the range 20%-50% – see ELN-P05 QA/QC tables for details; <10xPQL - RPD are higher as the results approach PQL and the estimated measurement uncertainty will statistically increase.

Matrix Spikes, LCS and Surrogate recoveries: Generally 70-130% for inorganics/metals (not SPOCAS); 60-140% for organics/SPOCAS (+/-50% surrogates) and 10-140% for labile SVOCs (including labile surrogates), ultra trace organics and speciated phenols is acceptable.

In circumstances where no duplicate and/or sample spike has been reported at 1 in 10 and/or 1 in 20 samples respectively, the sample volume submitted was insufficient in order to satisfy laboratory QA/QC protocols.

When samples are received where certain analytes are outside of recommended technical holding times (THTs), the analysis has proceeded. Where analytes are on the verge of breaching THTs, every effort will be made to analyse within the THT or as soon as practicable.

Where sampling dates are not provided, Envirolab are not in a position to comment on the validity of the analysis where recommended technical holding times may have been breached.

Measurement Uncertainty estimates are available for most tests upon request.

Analysis of aqueous samples typically involves the extraction/digestion and/or analysis of the liquid phase only (i.e. NOT any settled sediment phase but inclusive of suspended particles if present), unless stipulated on the Envirolab COC and/or by correspondence. Notable exceptions include certain Physical Tests (pH/EC/BOD/COD/Apparent Colour etc.), Solids testing, total recoverable metals and PFAS where solids are included by default.

Samples for Microbiological analysis (not Amoeba forms) received outside of the 2-8°C temperature range do not meet the ideal cooling conditions as stated in AS2031-2012.

Report Comments

pH/EC Sample #1 was out of the recommended holding time for this analysis.

IMPORTANT INFORMATION

Important Information about this Geotechnical Report

Scope of Work

The purpose of this report and any associated documentation is expressly stated in the document. This document does not form a complete assessment of the site, and no implicit determinations about Cardno's scope can be taken if not specifically referenced. Whilst this report is intended to reduce geotechnical risk, no level of detail or scope of work can entirely eliminate risk.

The nature of geotechnical data typically precludes auxiliary environmental assessment without undertaking specific methods in the investigation. Therefore, unless it is explicitly stated in the scope of work, this report does not provide any contamination or environmental assessment of the site or adjacent sites, nor can it be inferred or implied from any component of the document.

The scope of work, geotechnical information, and assessments made by Cardno may be summarised in the report; however, all aspects of the document, including associated data and limitations should be reviewed in its entirety.

Standard of care

Cardno have undertaken investigations, performed consulting services, and prepared this report based on the Client's specific requirements, data that was available or was collected, and previous experience.

Cardno's findings and assessment represent its reasonable judgment, diligence, skill, with sound professional standards, within the time and budget constraints of its commission. No warranty, expressed or implied, is made as to the professional advice included in this report.

Data sources

In preparing this document, or providing any consulting services during the commission, Cardno may have relied on information from third parties including, but not limited to; sub-consultants, published data, and the Client including its employees or representatives. This data may not be verified and Cardno assumes no responsibility for the adequacy, incompleteness, inaccuracies, or reliability of this information.

Cardno does not assume any responsibility for assessments made partly, or entirely based on information provided by third parties.

Variability in conditions and limitations of data

Subsurface conditions are complex and can be highly variable; they cannot be accurately defined by discrete investigations. Geotechnical data is based on investigation locations which are explicitly representative of the specific sample or test points. Interpretation of conditions between such points cannot be assumed to represent actual subsurface information and there are unknowns or variations in ground conditions between test locations that cannot be inferred or predicted.

The precision and reliability of interpretive assessment between discrete points is dependent on the uniformity of the subsurface strata, as well as the frequency, detail, and method of sampling or testing.

Subsurface conditions are formed by various natural and anthropogenic processes and therefore are subject to change over time. This is particularly relevant with changes to the site ownership or usage, site boundary or layout, and design or planning modifications. Aspects of the site may also not be able to be determined due to physical or project related constraints and any information provided by Cardno cannot apply following modification to the site, regulations, standards, or the development itself.

It is important to appreciate that no level of detail in investigation, or diligence in assessment, can eliminate uncertainty related to subsurface conditions and thus, geotechnical risk. Cardno cannot and does not provide unqualified warranties nor does it assume any liability for site conditions not observed or accessible during the investigations.

Verification of opinions and recommendations

Geotechnical information, by nature, represents an opinion and is based extensively on judgment of both data and interpretive assessments or observation. This report and its associated documentation are provided explicitly based on Cardno's opinion of the site at the time of inspection, and cannot be extended beyond this.

Any recommendations or design are provided as preliminary until verified on site during project implementation or construction. Inspection and verification on site shall be conducted by a suitably qualified geotechnical consultant or engineer, and where subsurface conditions or interpretations differ from those provided in this document or otherwise anticipated, Cardno must be notified and be provided with an opportunity to review the recommendations.

Client and copyright

This document is produced by Cardno solely for the benefit and use by the Client in accordance with the terms of the engagement. Cardno does not and shall not assume any responsibility or liability whatsoever to any third party arising out of any use or reliance by any third party on the content of this document.

Copyright in the whole and every part of this document belongs to Cardno and may not be used, sold, transferred, copied or reproduced in whole or in part in any manner or form or in or on any media to any person other than by agreement with Cardno.
