

TNG's Proposed Waste Incinerator

Why It Shouldn't Be Built

No More Incinerators Inc gratefully acknowledges the assistance of the National Toxics Network in obtaining the papers cited in this submission.

SUMMARY

1) TNG's proposal

The Next Generation NSW Pty Ltd (TNG) is proposing to build a waste processing facility and waste incinerator at Eastern Creek, burning solid materials collected from a range of domestic and industrial materials, to produce electricity.

2) **There is no difference in TNG's revised EIS and the proposed incinerator should not be allowed.**

TNG's proposal has been modified to exclude "Floc and chromate treated timber, **but include** alternate fuel sources such as Municipal Waste Organics Output (MWOO)¹. The NSW EPA has found that "MWOO contains a range of physical, [e.g. plastics] and other chemical contaminants that persist in the environment"². Given its composition this material should not be used as a fuel source as it would release a range of persistent organic pollutants (POPs) into the local environment.

3) **The ongoing and long-term health risks posed by this waste incinerator are unacceptable risk to the residents of Blacktown LGA and Greater Sydney.**

Today Eastern Creek is not just a commercial and manufacturing hub, but a highly urbanised area with large numbers of residents living within 8km of TNG's proposed waste processing plant and as such this represents a serious long-term health risk to all residents living in the Blacktown LGA and the Greater Sydney area generally.

4) **Burning plastic and other materials to reduce landfill is not an acceptable trade-off**

The major driving factor for this project is undoubtedly the Australian Government's legislation banning the export of our recycled plastics and while it may reduce the need to export recycled plastics, the emissions from the incineration of these plastics and other solid waste will cause severe, long-term impacts to the environment and to the health of residents living in the Greater Sydney area.

5) **Any waste generated will need to be TCLP tested and once landfilled this material will also need to be environmentally monitored permanently.**

The incineration of waste creates highly toxic ash, contaminated filter carbon and a range of pollutants which accumulate in the environment, food chain and people, can't be treated or recycled and must be contained in a hazardous waste landfill forever. Any PPE or other consumables used during maintenance activities would also have to be treated as hazardous waste and also stored in a hazardous waste landfill.

EPA 2019P1894

All of the heavy (clinker) and fly ash produced and each batch of spent reagents (e.g. activated carbon) generated during incineration will need to be tested prior to disposal using the US EPA's Toxicity Characteristic Leaching Procedure, (TCLP test)³.

The TCLP test is the NSW EPA's preferred methodology for the classification of waste and would most probably mean that all of this material would need to be disposed of as Hazardous Waste, which cannot be disposed of to a general landfill. This ash cannot be treated and has been shown to leach pollutants into the environment even when mixed with concrete.⁴

6) Waste incinerators need to be continuously monitored – not just spot sampled three of four times a year.

What is proposed has major adverse health implications. Incineration of waste creates dust particles which are less than 2.5 microns in size that can't be filtered out of the stack gases. These PM2.5 particles can carry toxic pollutants which, when inhaled, can lodge in the lungs and then migrate into the blood stream causing cancer and a range of other serious health effects⁵.

Heavy metals, dioxins and furans should be continuously monitored using an AMESA⁶ type or similar continuous sampler.

NOTE: AMESA (Adsorption METHOD for SAMpling of dioxins) samplers reflect current best practice for the continuous, long-term sampling of stack gases and would be carried out in addition to the current continuous monitoring of acid and other gases normally undertaken. ENVEA's AMESA sampler has been TÜV and MCERTs certified, ETV EPA approved and meets EU Standards EN 1948-1 and CEN/TS 1948-5.4

Several other EU-based companies also offer similarly certified samplers. For example, Gaset's automated dioxin sampling system also meets the European EN 1948-1:2006 standard.⁷

7) This proposal will not reduce greenhouse gas emissions.

Every tonne of mixed waste burnt produces approximately 1.5 tonnes of greenhouse gases. The bulk of current greenhouse gas emissions are created from rotting organic material in landfills which will not be recovered by TNG's process.

8) Promoting a circular economy is a viable alternative to the use of incineration to manage waste throughout Greater Sydney and NSW.

There is a viable, sustainable alternative which provides a win-win solution for the environment, jobs, the health of Sydney residents and solves the waste issue. The NSW government needs to adopt a Zero Waste policy. This will promote a robust recovery and

recycling industry creating a circular economy and a range of downstream manufacturing and service industries able to provide thousands of skilled, permanent employment opportunities across all sectors of the NSW economy.

The incineration of waste represents the greatest single threat to the creation of a sustainable, circular economy in NSW and a move back to the past where air pollution in the Sydney basin will inevitably become much worse, causing the adverse environmental and human health impacts that successive NSW governments have worked so hard, for so many years, to reverse.

THE PROBLEM

Some of the main issues of concern are:

1. The Sydney basin traps and concentrates pollutants

Figure 1 shows the typical morning and afternoon seasonal wind directions over the Sydney basin and Figure 2 clearly shows how the constant discharge of low-level particulates and pollutants from TNG's incinerator will build up across the Greater Sydney area which sits in a large geographical basin some 100km across.

With the Blue Mountains to the west the prevalent winds move any pollution back and forth across the Sydney basin, and when the right temperature conditions occur, this can create an inversion layer trapping any pollution and allowing it to accumulate over the Greater Sydney area.

The formation of inversion layers over Sydney has always been a problem and Photos 1, 2 and 3 show pollutants trapped under typical inversion layers that formed over the Sydney basin in the 60s and 70s, and even during a minor prescribed burn off in 2018.

2. Release of Persistent Organic Pollutants (POPs) into the environment

The fuel for TNG's incinerator will be sourced from construction, demolition & municipal waste streams such as Municipal Waste Organics Output (MWO). The NSW EPA has found that "MWO contains a range of physical, [e.g. plastics] and other chemical contaminants that persist in the environment"⁸. Given its composition this material should not be used as a fuel source as it would release a range of persistent organic pollutants (POPs) into the local environment contaminating the environment and surrounding communities.

This means that in effect there is no difference in TNG's revised EIS and the proposed incinerator should not be allowed.

The fuel stream will also contain a large range of plastics – including halogenated plastics e.g. PVC, which cannot be separated out and when burnt will produce dioxins and furans which are some of the most lethal Persistent Organic Pollutants (POPs) known.

NOTE: To stop this from happening the stated operating temperature of 850°C will need to be increased to more than 1100°C to prevent dioxins and other POPs forming. This will require much more energy to maintain the higher temperature and also much more expensive Inconel grades of steel to be able to withstand the higher operating temperatures and more corrosive environment.

⁸ NSW EPA (2019), Future use of mixed waste organic outputs, ISBN 978 1 925987 21 8 EPA 2019P1894

Dioxins or polychlorinated dibenzodioxins, (PCDDs) are considered to be so toxic that in 2012 the USEPA announced that the safe limit for human consumption is 0.7 picograms Toxic Equivalence (TEQ) per kilogram of bodyweight per day. This is a tiny quantity – one picogram is 10^{-12} grams.

Dioxins are only one of a range of highly toxic compounds that can be emitted by waste incineration. Many of these compounds can bioaccumulate in the marine and land environment, i.e. they become more concentrated as they are passed from one species to the next through the food chain. They contaminate the air we breathe and the food we eat, and damage reproductive, neurological and immune systems, interfere with hormones and cause cancer.

3. Scrubbing stack emissions will not remove ultrafine and nanoparticles

Experience has shown that even with the most sophisticated scrubber and pollution control equipment installed, it is notoriously difficult to maintain the optimum furnace conditions to minimise the production of highly toxic pollutants such as dioxins. This is because the conditions required to form dioxins (and other pollutants) are not fully understood. Dioxins may be formed at either low or high temperature and formation reactions do not go to completion⁹.

In addition, uncontrolled emissions of dioxins and other persistent organic pollutants can occur during bypass events such as start-up, shut-down and maintenance events. These transient events are not usually measured or reported to regulators yet represent a significant pollution impact for the surrounding community through contamination of the environment and food chain, e.g. eggs¹⁰

4. The ash and other by-products produced by waste incineration are highly toxic

The scrubber liquid, ash and dust produced by high temperature incineration are also highly hazardous to workers and the environment and require special treatment and must be disposed of as hazardous waste. These wastes would need to be disposed of in double encapsulated clay lined cells and monitored forever as they have the potential to cause serious environmental pollution if leaching occurs.

Numerous studies have been carried out on dioxins and other POPs entering the environment. For example, dioxins in incinerator ash used to make paving in residential areas in the UK have been found in free range poultry¹¹ and in mothers and their breast-fed infants living near a 10-year-old municipal waste incinerator (MWI) in China¹².

5. Ever increasing greenhouse gas emissions

Waste incineration produces large amounts of carbon dioxide and nitrous oxides which are potent greenhouse gases that contribute significantly to global warming and ozone depletion. History shows that waste incinerator/co-gen plant operators seek ever increasing quantities of

waste to burn causing greenhouse gas emissions to steadily increase. There is no savings of greenhouse gases as claimed.

Every tonne of mixed waste burnt produces approximately 1.5 tonnes of greenhouse gases. TNG's waste processing and incineration facility will not reduce greenhouse gas emissions by reducing the amount of waste going to landfill as the bulk of greenhouse gas emissions are created from rotting organic material which will not be recovered by TNG's process and go to landfill anyway.

6. The collapse of the recycling industry

Experience in Europe has shown that high temperature incineration has undermined the recycling industry causing it to collapse. This is because facility operators insist on contracts that force local councils and other municipal authorities to supply minimum quantities of waste or face contractual penalties. In effect the use of high temperature incineration discourages the collection and reuse of recyclable materials resulting the recycling industry becoming unsustainable.

Municipal and state governments are also vulnerable to waste incineration contracts which are lengthy (30 years) and lock in fuel feedstocks. This has the effect of diverting waste resources away from higher order waste management outcomes like reuse and recycling. The financial risk for municipalities are significant as they are required to meet their contracts whether they have the waste supply volumes or not.

The ongoing environmental and health issues associated with waste incineration has led to waste management through recovery and recycling being preferred as a more ecologically sustainable and cost-effective waste management solution and the European Commission has:

- Legislated to discourage and decommission waste incineration in the EU¹³
- Removed all renewable energy and industry subsidies that the industry relies upon to be viable¹⁴ and
- Announced that the EU taxonomy will not include waste incineration¹⁵ in recognition of the significant environmental impacts HT incineration causes and threat it poses to the creation of a robust circular economy¹⁶.

THE SOLUTION

To avoid the detrimental impacts of TNG's proposed waste incinerator to the local and surrounding environment and to the health of Blacktown LGA and Greater Sydney residents TNG's revised EIS must be rejected and their proposal refused.

In addition, the NSW Government must actively promote and adopt a Zero Waste City model¹⁷ that includes the expansion of the existing waste resource recovery and recycling industry to recover and recycle a range of resources to form a sustainable, circular economy,

¹³ European Commission, 26 January 2017, The role of waste-to-energy in the circular economy, Brussels.

¹⁴ The REGI committee report excludes from the scope of the Cohesion Fund "investment in facilities for the treatment of residual waste with the exception of outermost regions and in case of state-of-the-art recycling solutions in line with the principles of the circular economy and the waste hierarchy fully respecting the targets laid down in Art 11(2) of Directive (EU) 2008/98 and provided that Member States have established their waste management plans according to Art. 29 of Directive (EU) 2018/851"

which in turn will drive the creation of a solid manufacturing base and 1000's of permanent, skilled jobs for NSW.

Various government incentives should also be provided to foster a viable, robust recycling industry able to provide thousands of new, permanent job opportunities ranging from entry level through to senior management.

By doing this NSW (and Australia) will benefit from:

- Significantly reducing the quantity of waste requiring landfill
- Significantly reducing greenhouse gas emissions
- Protecting the long-term health of not only Blacktown LGA, but all Sydney residents
- Maintaining and enhancing the existing waste recovery and recycling industry and
- Provide skilled, permanent job opportunities for all Australians.
