1.0 Introduction

1.1 General Project Description

The Crookwell 3 Wind Farm (the project) is a wind energy facility proposed to be constructed by Crookwell Development Pty Ltd (CDPL) in the Southern Tablelands of New South Wales (NSW), approximately 17km southeast of the Crookwell Township. The project is located within the Upper Lachlan Shire Council Local Government Area.

The project is to be located on two separate land parcels known as Crookwell 3 East (1,100 ha) and Crookwell 3 South (400 ha) (the site). It includes the construction and operation of up to 30 wind turbines and related facilities including up to 30 kiosks for the housing of transformers and switchgears, an underground cable network linking the turbines within the site, access tracks, concrete pads, and up to three wind monitoring masts. The cable network will be connected (either by underground or aboveground cables) to an already approved national electricity grid substation located on the adjacent Crookwell 2 site.

1.2 Background to this Document

AECOM Australia Pty Ltd (AECOM) has been engaged by CDPL to prepare a Decommissioning and Rehabilitation Plan (DRP) for the project. Under the Department of Planning and Infrastructure’s (DP&I) Draft NSW Planning Guidelines: Wind Farms (2011), it is a requirement that the Environmental Assessment for the project includes a DRP.

The purpose of this DRP is to identify the methodology that CDPL will use to mitigate potential impacts resulting from the cessation of operation of the facility at the end of the project’s useful economic life. This plan provides an outline of the stakeholder and landowner consultation, expected operational life, dismantling, land rehabilitation, funding arrangements, timeframe, responsibility and review of the plan associated with the decommissioning of the Crookwell 3 Wind Farm.

2.0 Consultation

2.1 Consultation undertaken to date

2.1.1 Consultation with Landowners

The land within which the project site is to be located is owned by three landowners. All landowners were initially contacted and consulted about the project and issues of decommissioning and rehabilitation discussed at the early stages of the project.

A lease agreement was later presented to each landowner, which reflects that the decommissioning of the wind farm is the sole responsibility of CDPL. Provisions in the lease agreement relating to decommissioning and rehabilitation are summarised in Appendix A. The entered lease agreements provide CDPL with leases of the site for a term of 30 years, and grant CDPL with the opportunity to extend the lease for a further 30 years.

Prior to each lease being executed with the landowners, this DRP was discussed and agreed with all landowners. During these discussions, CDPL affirmed their commitment to this plan. Initial feedback from the landowners was generally positive with no objections to the project. A summary of the landowners’ responses follows:

- Two landowners were satisfied with the document and had no additional input; and
- One landowner formulated a concern about bare soil being left exposed during the decommissioning process, and the necessity to address this issue during the rehabilitation of the site. The landowner stressed that bare soil in pasture areas leads to weed proliferation and in turn to wool contamination and further land degradation. This issue has been considered and addressed in this plan.
2.1.2 Other Consultation
CDPL has been in consultation with the Upper Lachlan Shire Council (ULSC) from the early phase of the project, including general discussions relating to the construction, operation and decommissioning of the project. One issue that was raised by Council was that pertaining to the rehabilitation of Council owned infrastructure such as local roads and bridges during the decommissioning phase. These concerns and requirements are highlighted in the Council’s latest Development Control Plan, and also in their submission to the NSW draft Planning Guidelines for Wind Farms (28 Feb 2012). However whilst CDPL acknowledge the Council’s conservative stance on these matters, there is no current evidence to support Councils concerns.

This issue relating to the management of roads and infrastructure has been addressed in Sections 4.1.4 and 5.2 and is to be included in the Traffic and Transport Management Plan.

2.2 Consultation Prior to Decommissioning Works
CDPL will undertake further consultation with stakeholders prior to and during the decommissioning process. Stakeholders to be consulted will include (but not necessarily limited to) the Upper Lachlan Shire Council, landowners and local community neighbours. Other relevant stakeholders will be identified and consulted as required, including regulatory authorities, industry neighbours\(^1\) and community groups.

The consultation process will be open and transparent, and its objectives will be to (as a minimum):

- Provide the timing of the proposed decommissioning works;
- Present the nature of the proposed decommissioning works, including the turbines dismantling procedure and the proposed land rehabilitation works and objectives;
- Obtain stakeholders comments on the decommissioning works and address any concerns (including providing timely and responsive feedback and conflict resolution); and
- Seek ideas to maximise the net benefit to the community during the decommissioning process.

The consultation activities to be undertaken may include:

- Meetings with the Upper Lachlan Shire Council;
- One-on-one consultation and discussion with individual landowners; and
- Information session or ‘Open House’ forum to introduce the decommissioning activities to the local community; and
- A newsletter mail-out to all residents within 5km of the project site providing information on the decommissioning activities.

3.0 Operational Life of the Wind Farm

As noted above, the lease agreements held by CDPL are for a period of 30 years, with an option for an additional 30 years. The operational life of the Crookwell 3 Wind Farm is therefore expected to be of at least 30 years.

Megawatt-scale wind turbine generators available on the market today have a design life expectancy of 20 to 25 years depending on site conditions. The tubular steel towers supporting the generators are of simple design and with basic routine maintenance could serve many years beyond the life expectancy of the generators.

During the design life period or as the turbine generators approach the end of their expected life, the nacelle components and the blades of the turbines may be replaced or renewed, or the turbine may be repowered to utilise newer and more efficient technology available at that time. This will economically drive the replacement of the existing generators and thus prolong the economic life of the project until at least the end of the lease agreement period.

Any continuation of the project may take the form of one of the following:

- Extended operation of the original turbines;

\(^1\) Includes though not limited to contractors who may be engaged in the decommissioning process, other wind farm proponents operating in the Upper Lachlan Shire Council area and energy distribution and supply agencies.
- Turbine replacement with the similar model that has newer and more efficient technology; or
- Turbine replacement with a different model that would be subject to the requisite approvals being obtained at that time.

During the operational life of the wind farm, CDPL will keep independently verified annual records of each wind turbine electricity generation production. These records will be made available to the DP&I on request.

Once the wind farm reaches the end of its useful economic life, the project would be decommissioned.

4.0 Dismantling Process Description

Unless the relevant electricity network operator or landowner requests that certain wind farm infrastructure be retained on land, it will be removed and the land restored to its previous condition or better. The following sections summarise how each component of the wind farm infrastructure will be dismantled and decommissioned.

4.1 Dismantling

4.1.1 Turbines, Kiosks and Concrete Foundation

The wind turbines and kiosks will be dismantled in the reverse of the erection sequence. A large crane will be brought to the site and assembled, along with support cranes and equipment. The turbines will be dismantled using standard best management practices. The work sequence for dismantling and decommissioning a particular tower site will most likely proceed as follow:

- Assemble and stage crane on pad at turbine;
- Install erosion and sediment controls as required;
- Disconnect electrical connections;
- Remove rotor and set on ground;
- Remove nacelle and set on ground;
- Remove turbine tower sections and stage on ground;
- Remove kiosks;
- Haul off turbine and kiosks components;
- Remove concrete foundation (to 1m below ground surface);
- Backfill foundation area;
- Rehabilitate foundation area; and
- Maintain the site in context of sediment control and weed management.

After removal the wind turbines will be either scrapped or transported to another site for reuse. Any component that can neither be reused nor salvaged will be recycled or disposed of.

If the turbines are resold for reuse, the rotor, nacelle and tower sections will be dismantled and transported from the site in a manner similar as was used to deliver the turbines to the site.

If the turbines are not sold for reuse, they will be disassembled into smaller components and sold for scrap to a scrap metal recycling company. This procedure will take place either at a central lay down area or on the concrete foundation below the turbine. Critical lift plans will be developed specifically for each major turbine component. The hub, blades and nacelle will be broken down and stripped of high value components. Cabling internal to the towers will be removed and scrapped to recover the high value copper conductor materials. Tower sections would be cut into transportable sections for delivery to the scrap metal recycling company. Kiosks would be stripped of high value components.

The concrete used for the turbines foundation pads will be sent to a concrete recycling facility.
4.1.2 Other Ancillary Facilities

All ancillary facilities related to the wind farm and located on the landowners’ property would be removed. Sheds and any portable buildings will be transported off site for sale, recycling or disposal.

A demolition contractor will remove decommissioning debris to a licensed disposal facility permitted to operate under the current and applicable regulations at the time decommissioning occur.

4.1.3 Electrical Infrastructure

All overhead power line poles and conductors connecting the wind farm to the national electricity grid substation at the Crookwell 2 site will be removed. The control room facilities and equipment not required for the operation of the substation will be removed. As far as possible, all materials and components (e.g. steel, conductors, switches, transformers, etc.) will be reused, sold as scrap, recycled, or re-purposed to the maximum amount economically practical. Any other components will be hauled to approved disposal facilities. Any ground disturbed as a result of these activities will be rehabilitated.

It is anticipated that the removal of underground cables would not be cost-effective and would significantly disturb the landscape and the farming activities by creating large trenches. In order to minimise the environmental and agricultural impacts, the underground cable network would therefore not be removed as part of the project decommissioning. Rather, all cables will be terminated at the end of the runs (including watercourse crossing conduits), the ends will be capped with appropriate insulation and buried to a depth of approximately one metre below the ground surface, and left in place. No known hazards exist from the presence of capped unused/inert underground cables. Any land disturbed by these activities would be rehabilitated.

4.1.4 Access Roads

Consultation with the host landowners will be conducted to determine whether access tracks and access roads will be decommissioned. If landowners consider the tracks to be useful to their farming activities (or others), they will be left in place and will remain part of the on farm infrastructure. Otherwise, access tracks and access roads will be removed and the areas rehabilitated.

4.2 Transportation

All of the turbines will be dismantled on site and broken into smaller pieces to allow for easier transportation. If the pieces cannot be transported off site immediately, they will be stored on site on a lay down area until they can be removed. A central lay down area (of up to 2ha) may therefore be created, including topsoil removal, levelling and compacting. Any ground disturbed by the creation of the lay down area would later be rehabilitated.

Off-site transport of pieces and components would be undertaken in accordance with a Traffic and Transport Management Plan. This may be the Traffic and Transport Management Plan used for construction which will be reviewed and updated to reflect the decommissioning traffic movements. The location of scrap metal merchants and other recycling and disposal facilities to be used will be determined closer to the time of decommissioning.

Current local options identified in the vicinity of the project area who may be likely candidates are:

- Southern District Metal Recyclers – 57 Wayo Street, Goulburn.
- Goulburn Sand & Soil – 282 Carrick Road, Goulburn.
- Woodland Bioreactor – 619 Collector Road, Tarago.

4.3 Waste Minimisation Strategy

4.3.1 Waste Management

All waste management will be undertaken in accordance with the NSW EPA’s Guideline Assessment, Classification and Management of Liquid and Non-Liquid Wastes (1999), or any other relevant guidelines at the time of decommissioning.

As an overarching principle, the waste minimisation hierarchy of avoid/reduce/reuse/recycle/dispose will be applied wherever possible to all decommissioning wastes. Any waste that is unable to be reused, reprocessed or recycled will be disposed of at a facility approved to receive that type of waste.

2 Decommissioning costs presented in Section 6.1 and Appendix B were based on materials being transported to Canberra for recycling or disposal. These facilities are provided by way of local options.
4.4 Recovery of Wind Turbines

As previously mentioned (refer to Section 4.1), wind turbines will be either reused or recycled. If they are sold for reuse, the turbines will be dismantled and delivered off-site. If they are recycled, the following will apply. The objective of the recovery strategy will be to maximise the salvage potential of each turbine and extract value through recycling and reusing its components.

4.4.1 Metallic components

The tower, nacelle and hub components of the turbines primarily consist of metals including steel, aluminium and copper (Ancona and McVeigh, 2001). The turbines will be disassembled on site and all metal components will be transported and sold to a local scrap metal recycling facility.

4.4.2 Turbine blades

Unlike the rest of the turbine, the blades are constructed from composite materials including glass fibre, carbon fibre, polyester and epoxy (Ancona and McVeigh, 2001). In order to be recovered, these materials require a more complex recycling process due to their inherent heterogeneous nature (Yang et al, 2011). The aim of the recycling process of composite materials is to separate the polymer (resin) and fibre composites. Once separated, the resins are usually used for energy production while the fibre recyclates can be reused or recycled. There currently exist five main methods for recycling composite materials, including mechanical, thermal, oxidation, chemical and cement kiln routes. These processes are presented in Table 1.

<table>
<thead>
<tr>
<th>Process</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mechanical</td>
<td>Blades materials are crushed to reduce the size of the pieces to 50 micrometres in size (Pickering, 2006). This process ‘pounds’ the resins out of the fibres. A grading process is then used to separate the finer (resin) and coarser (fibre) materials.</td>
</tr>
<tr>
<td>Thermal – Pyrolysis</td>
<td>Blades materials are heated to 450°C to 700°C without oxygen, which converts the resins into gas while the fibres remain inert. The energy generated (gas) can be used in electricity production. Fibres can be later recovered and reused or recycled.</td>
</tr>
<tr>
<td>Oxidation in fluidised bed</td>
<td>The fluidised bed process is the most well-known implementation. It consists of combusting the polymeric matrix in a hot and oxygen-rich air flow of 450°C to 550°C. The polymer breaks down and vaporises, releasing the fibres which are carried out into the gas stream. The fibres are separated out and the resin products are fully oxidised in a combustion chamber, where the heat energy can be recovered.</td>
</tr>
<tr>
<td>Chemical – Solvolysis</td>
<td>Alcohols (propanol for carbon fibre, methanol for glass fibre) in a supercritical state are used to dissolve the resin from the fibre composites. The polymeric resin is decomposed into oils which free the fibres for collection. This process allows the chemicals in the resin to be reclaimed.</td>
</tr>
<tr>
<td>Cement kiln route</td>
<td>Composite materials are fed into a cement kiln. Approximately two-thirds of the material is transferred into raw materials for cement and one third, the organic part (resin) is burnt, generating energy.</td>
</tr>
</tbody>
</table>

The optimal solution for the recycling of the turbines blades will be determined and selected closer to the decommissioning time. It is noted that the technology in wind turbine manufacture as well as in recycling processes evolves quickly. CDPL is committed to staying well-informed of new research and to embracing new technologies as they become available. In this light, if technology advances at the time of decommissioning allow for more efficient and cost-effective resource recovery, they will be given preference.
5.0 Land Rehabilitation

5.1 Rehabilitation Objectives

The general objective of the rehabilitation activities is to return the site to pre-construction conditions and contours, which is currently dominated by improved pastures for the purpose of sheep and beef cattle grazing. Specific rehabilitation outcomes will be developed in consultation with the landowners.

The environmental assessment for the project (Tract Consultants, 2012) estimates that 2.3ha of native vegetation will be removed for the project. CDPL is committed to re-instating this vegetation as part of the rehabilitation activities, while all other land disturbed will be stabilised and re-seeded with native grasses consistent with the existing surrounding rural/agricultural landscape.

5.2 Areas to be rehabilitated

Any land disturbed during the construction, operation or decommissioning of the wind farm will be rehabilitated, unless agreed with the landowners. It is expected that the following areas will be restored and rehabilitated:

- The foundation area of each wind turbine (each pad is approx. 20m x 20m);
- The on-site central lay down area (approx. 2ha);
- The holes left in the ground following the removal of overhead power-line poles;
- Wind farm control room facilities and transformer bay area and
- Access roads and access track, as agreed with landowners.

5.3 Rehabilitation Process Description

All excavated areas will be filled with clean compatible sub-grade material compacted to a density similar to the surrounding area and contoured to match the surrounding landform. Topsoil would then be replaced and compacted to match the density and consistency of the immediate surrounding area.

Unexcavated areas compacted by equipment used in the decommissioning process will be tilled in a manner adequate to restore the topsoil and sub-grade material to the density consistent with the surrounding area.

Areas to be returned to pasture will be seeded with a seed mix agreed upon with the landowners in order to maintain consistency with the surrounding agricultural uses and to mitigate colonisation of these areas by weed species. Typical species mix will promote species diversity and include legumes species.

Areas to be returned to trees and shrubs will be seeded with a native species mix promoting species diversity and containing fast germinating species. Where possible, the seeds will be sourced locally. The vegetation to be re-established will be aligned to an endemic ecosystem or local plant communities.

In order to promote plant establishment, all revegetation areas will be treated with fertiliser at the time of sowing.

In all areas rehabilitation will include, as reasonably required, levelling, terracing, mulching and other necessary steps to prevent soil erosion, to ensure establishment of desirable vegetation, and to control weeds and vertebrate pests.

At the completion of decommissioning CDPL will provide a one off payment (amount to be determined) to the host landowner for the coordination of the monitoring and maintenance program across their lands. This approach to monitoring allows for the project site to experience seasonal changes and for determining if additional restoration is required, including the management and control of weed species.

6.0 Funding Arrangements

Financial assurance for the decommissioning costs will be fully established for the entire useful economic life of the project. The decommissioning funding plan for the project is summarised below.
6.1 Decommissioning Costs

The net cost to decommission the Crookwell 3 Wind Farm is equal to the cost to perform the decommissioning tasks described in Section 4.0, less the resale value of the turbines (either for reuse or for scrap). Costs estimates have been produced as part of this DRP for the dismantling, rehabilitation and resale of the wind turbines. They are provided in Appendix B.

Estimates were based on recent industry examples and using available information from a variety of credible industry sources, and are considered to be the current dollar value (at the time of approval) of salvage value and removal costs.

Several assumptions have been made and foreseeable risks identified during the cost estimation process (refer to Appendix B). It is noted that the level of confidence in these estimates are only as good as the reliability of the information on which they are based. There does not currently exist any real example of such estimations previously produced in Australia; as such an inherent level of uncertainty surrounds these estimates.

6.1.1 Decommissioning costs with turbine salvage

The estimated value of the turbines was based solely on its value as scrap steel, which by far represents the greatest value of all metal components of the turbines. Based on the current values for recycled steel, the net cost to decommission the wind farm was estimated to be of $6,650 per wind turbine (refer to Appendix B).

However, because it did not separate the scrap value of all constituent materials, this estimated is considered very conservative considering approximately 20-30 tonnes of the total weight of a turbine is copper, which would yield a higher value than steel. The salvage price of other individual components such as blades, gearbox, transformer, switchgear (etc.), was also excluded.

6.1.2 Decommissioning cost with turbine resale

From the estimates, it is evident that the greatest value of the decommissioned wind turbines would be realised by selling the turbines for reuse. The estimated turbine resale value ($100,000 per turbine) would exceed the estimated decommissioning costs ($6,650 per turbine) (refer to Appendix B), and thus, under the assumption that wind turbines are resold, there would be no net cost to decommissioning the wind farm.

At the time of writing this plan, it is therefore expected that decommissioning funds will be provided using this option.

6.2 Ensuring Decommissioning Funds

Current discussions with turbines suppliers and experience in the USA and Europe and the local markets indicate that it is likely that the project will have a full ten years warranty. During this period the risk of the project requiring decommissioning is considered extremely low and the cost would be covered by the turbine supplier.

Forecast annual revenue for the project indicates that the expected ‘break-even’ point for the capital investments would occur at year 10 of the project’s operational life. If this is less than ten years → costs covered by warranty. If more than 10 years: for the period between year 10 and break-even point → costs = [(decommissioning costs + what’s left to pay on turbines) – (scrap value from salvage)]

Beyond the 10-year warranty period and the 10 year ‘break-even’ period, decommissioning funds will be ensured through the resale (for reuse) of the wind turbines to other providers. No bond is therefore required at this time.

6.3 Review

As part of each review of the DRP (to be undertaken 5-yearly, refer to Section 9.0), the funding plan will be reviewed by an independent, credible and reputable service provider to ensure the funds raised from the salvage of the turbines are still sufficient to cover the costs of decommissioning. This review will re-assess the dismantling/decommissioning costs and/or adjust the original costs for inflation. If a shortfall is identified at that time, the proponent will then establish a dedicated internal fund to supplement this shortfall and which will be used to cover the net costs for decommissioning. This internal fund will be put aside within the parent company (i.e. Union Fenosa Wind Australia) rather than the special purpose vehicle CDPL, and will be permanently accessible.
7.0 Timing

CDPL commits to undertaking all decommissioning and rehabilitation works outlined in this plan within the 18 months after the end of Crookwell 3 Wind Farm’s operational life.

During the operational life of the project, it is possible that individual turbines will cease operating for extended periods of time if they are malfunctioning and need to be repaired. Depending on the market availability of specific wind turbine parts, which regularly have to be sourced overseas, some turbines may be inactive for periods longer than twelve month before they can be repaired. Any turbine that cannot be repaired and is deemed permanently unworkable (due to environmental, social, economic or other unforeseen issues) will be decommissioned and dismantled, and the site rehabilitated within 18 months.

Although this DRP strictly applies to the Crookwell 3 Wind Farm only, it is noted that the project’s site is adjacent and connected to the Crookwell 2 site. Considering this proximity, CDPL may investigate the possibility of coordinating the decommissioning of wind turbines on both sites where possible, and if decommissioning timeframes align.

8.0 Responsibility

CDPL (or any future owner) will be fully responsible for the decommissioning of the project. This is supported by the provisions in the lease agreements which will be executed between CDPL and the landowners prior to the construction commencement (refer to Appendix A).

9.0 Review of this Plan

This DRP will be reviewed, and revised as required, every 5 years for the duration of the project. During each review, the effectiveness of the plan will be re-assessed against its objectives, and cost estimates and funding arrangements will also be independently reviewed.

Examples of why the plan may need to be revised include:
- A modification to the condition of the Approval;
- Deficiencies being identified;
- Changing environmental requirements;
- Change in legislation; and
- Improvements in knowledge or technology become available.

Any major changes to this plan will be undertaken in consultation with the appropriate regulatory authorities and stakeholders.

This DRP, as well as all subsequent reviews, will be made public and placed on CDPL website. CDPL will also provide a copy of the revised DRPs to the relevant consent authority at the time.

10.0 References

Appendix A

Decommissioning Provisions within the Lease Agreements
The Lease Agreements with the landowners each contain the following provisions:

Clause 5.3 Lessee must observe Law and Rules:
The Lessee must comply with the law, any Authorisation and any notice from any authority that requires the Lessee to do or not do anything concerning the Premises, the Lessee’s use of the Premises, or this lease (for example, laws relating to occupational health and safety and environmental matters)

Clause 10.4 Consequences of termination or expiry:

(a) If the Lessee serves a notice of termination under clause 10.1(a) as a consequence of a default arising under clause 9.1(a) or 9.1(b), the Lessee may, at the same time, serve notice on the Lessor electing to remove all or part of the Improvements from the Premises provided that the Lessee must repair any damage caused by that removal.

(b) If:

(1) the Lessee serves a notice of termination under clause 10.2 or under clause 10.1(a) as a consequence of a default arising under 9.1(c)

(2) the Lessor serves a termination notice under clause 10.1(a);

or

(3) this lease expire through the effluxion of time,

then the Lessee must promptly remove all of the Improvements from the Premises and reinstate the Premises to the standard referred to in clause 10.5, and extinguish any easements on the Land.

(c) Without prejudice to any obligations under clause 10.4(a) or 10.4(b), once this lease has been terminated the Lessee is absolutely discharged from its future obligations under this lease, provided that, if the Lessee has an obligation under clause 10.4(b) to remove all Improvements from the Land and repair any damage caused by that removal, or the Lessee elects to remove Improvements from the Land under clause 10.4(a), then the Lessee must continue to pay Rent until the relevant Improvements have been removed and the Land has been repaired.
Clause 10.5 Handing back Premises:

In addition to any obligations the Lessee may have under clause 10.4, within 6 months of the end of this lease, the Lessee must give back the Premises to the Lessor in a condition consistent with the Lessee’s obligations under this lease, to the reasonable satisfaction of the Lessor, except for fair wear and tear.

**Notes & Assumptions**

- Rotors are dismantled by the small crane prior to arrival of the base tower crew
- For simplicity it is assumed that dismantling crews work at the rate of 4 WTGs per week
- Towers are in 3 sections
- Labour rates include vehicles, LAFHA, etc
- Labour is assumed to be 10 hours per day at $70/h, 6 days per week
- The site is 120km from Canberra where the scrap steel will be delivered
- The site is 210 km from Sydney
- Other assumptions are embedded in the above tables such as tower weight etc
- Potential scrap value of cabling and other equipment not considered
- The value of scrap metal has a very large impact and is very variable
- The method of dismantling is assumed to be the reverse of installation, however other methods such as blasting may be significantly cheaper.
Wind Turbine De-commissioning Costs - Dismantling and Resale

Total Turbines 30

SALE OF TURBINES
Total for Farm $/WTG Notes
Based on research of advertised used turbines $-3,000,000 $-100,000 See notes below

REMOVAL OF MAINTENANCE FACILITY
Total for Farm $/WTG Notes
Disconnect Services, remove buildings and tanks etc $30,000 $1,000

LAND REINSTATEMENT
Total for Farm $/WTG Notes
grading, re-seeding, etc $40,000 $1,333

LOGISTICS
Total for Farm $/WTG Notes
20t Truck Load 20 $2,000 $40,000

TOTAL DECOMMISSIONING COSTS
Wind Farm $/WTG
$-1,730,000 $-57,667

Notes
There are some points which lead us to the conclusion that the value of the turbines at 20 years of life will be significantly less than suggested in the above $/kW data:
1. The trade of used turbines in Australia will be more difficult that in Europe or the US where they are closer to markets likely to buy used units.
2. The Turbines at this wind farm will older (20+ years) than the average of the above
3. At the time that these turbines are decommissioned, there will also be many others being decommissioned at the same time, flooding the market.
4. As turbines go past their design life, the costs of installing them on a new site including transport, balance of plant etc can reduce the value to below zero and they may become a liability only.
